**Review of Japanese albacore catch data for the North Pacific albacore stock assessment in
April 2014**

by

Keisuke Satoh, Takayuki Matsumoto and Koji Uosaki

Summary

This document report Japanese albacore catch data and procedure for creating the catch data to apply to the North Pacific albacore stock assessment in April 2014. Procedure for creating the data was almost the same as the method applied for previous stock assessment (Matsumoto and Uosaki 2011) but it was slightly modified depending on changes of fishery definition which was agreed in the ISC albacore data preparation meeting in Nov. 2013.

1. Introduction

The data preparatory meeting in Nov. 2013 reached agreement for fishery definition applied to the North Pacific albacore stock assessment in April 2014, which were different with the fishery definitions applied to the previous stock assessment in 2011 (Anon. 2013). The aims of the document were to (1) report Japanese albacore catch data in accordance with the new fishery definitions; (2) summarize the procedures for creating the catch data.

2. Materials and method

Principal fishery statistics for the catch data were logbook and SID report. The logbook mandatory submitted by fishermen has been compiled at National Research Institute of Far Seas Fisheries (NRIFSF). Logbook database for longline, pole-and-line, driftnet (gillnet) and purse seine were used. The SID report is the annual report of catch statistic on fishery and aquaculture published by the Statistics and Information. This report provides comprehensive statistics for Japanese fisheries including annual catch by species and kind of fishery. Other information about fishery statistics were also used to breakdown annual catch to quarterly catch for Japanese miscellaneous catch. The detail of data source and procedures for creating the catch data was described in Matsumoto and Uosaki (2011).

¹This working paper was submitted to the ISC Albacore Working Group Intercessional Workshop, 14-18 April 2014, held at the Southwest Fisheries Science Center, La Jolla, California, USA. Document not to be cited without the author's permission.

3. Results

Geographical location, unit and period of the catch data for each fishery definition were summarized in Table 3 in the report of the data preparatory meeting in Nov. 2013. We extracted the information about Japanese fishery from the Table 3 and add some information about data source and references described the procedures creating the catch data. In addition, the location for north and south area of JPN LL EPO was assigned as $>=25$ and $<55^{\circ}\text{N}$ for the northern area, and $>=10$ and $<25^{\circ}\text{N}$ for the southern area according to discussion in the data preparatory meeting. Japanese albacore catch data in accordance with the new fishery definitions were shown in **Table 2**.

There were four catch series for Japanese longline fisheries due to two kinds of the catch units (number, weight) and two kinds of fish size (small, large). In specific area ($25\text{-}35^{\circ}\text{N}$ & $130\text{-}140^{\circ}\text{E}$) Japanese longline fishery is more likely to catch small sized fish, and outside the specific area the fishery have a good chance to catch large sized fish. The data source for number based catch data were logbook database of offshore and distant longline (vessel size is large). The number based data series were breakdowned according to inside and outside of the specific area. The data source for weight based catch series were logbook database of coastal longline (vessel size is small) and the SID report. The weight based catch series were created by the procedure of previous reports (Matsumoto and Uosaki 2011, Matsumoto et al. 2013) with slight modification for the setting of the specific area (**Fig. 1**).

After the data preparatory meeting the working group has continued to discuss the fishery definition of the stock assessment via e-mail. During these discussions it is suggested that JPN LL-large is appropriate for splitting southern and northern area because of larger fish (ca >120 cm) had been caught in the southern area before around 1992 (detail in Kiyofuji et al 2014). Therefore catch time series before 1992 for JPN LL-large split by 20N were also provided (**Table 3**). The annual proportion of the southern area to total geographical area (southern + northern) for weight based (F6_JP_LLL_wt) is constant (9.1%) thorough time period because the proportion of weight based catch before 1993 was average proportion for 1994 to 1997. The average proportion for number based catch (F7_JP_LLL_num) from 1966 to 1993 was low (8.3 %) except for high proportion more than 10% from 1970 to 1976 (**Fig 3**)

Procedure for developing quartely catch data of JPN LL-small (fleet ID 3) and JPN LL-large (fleet ID 6) of Japanese coastal longline vessel (1994-)

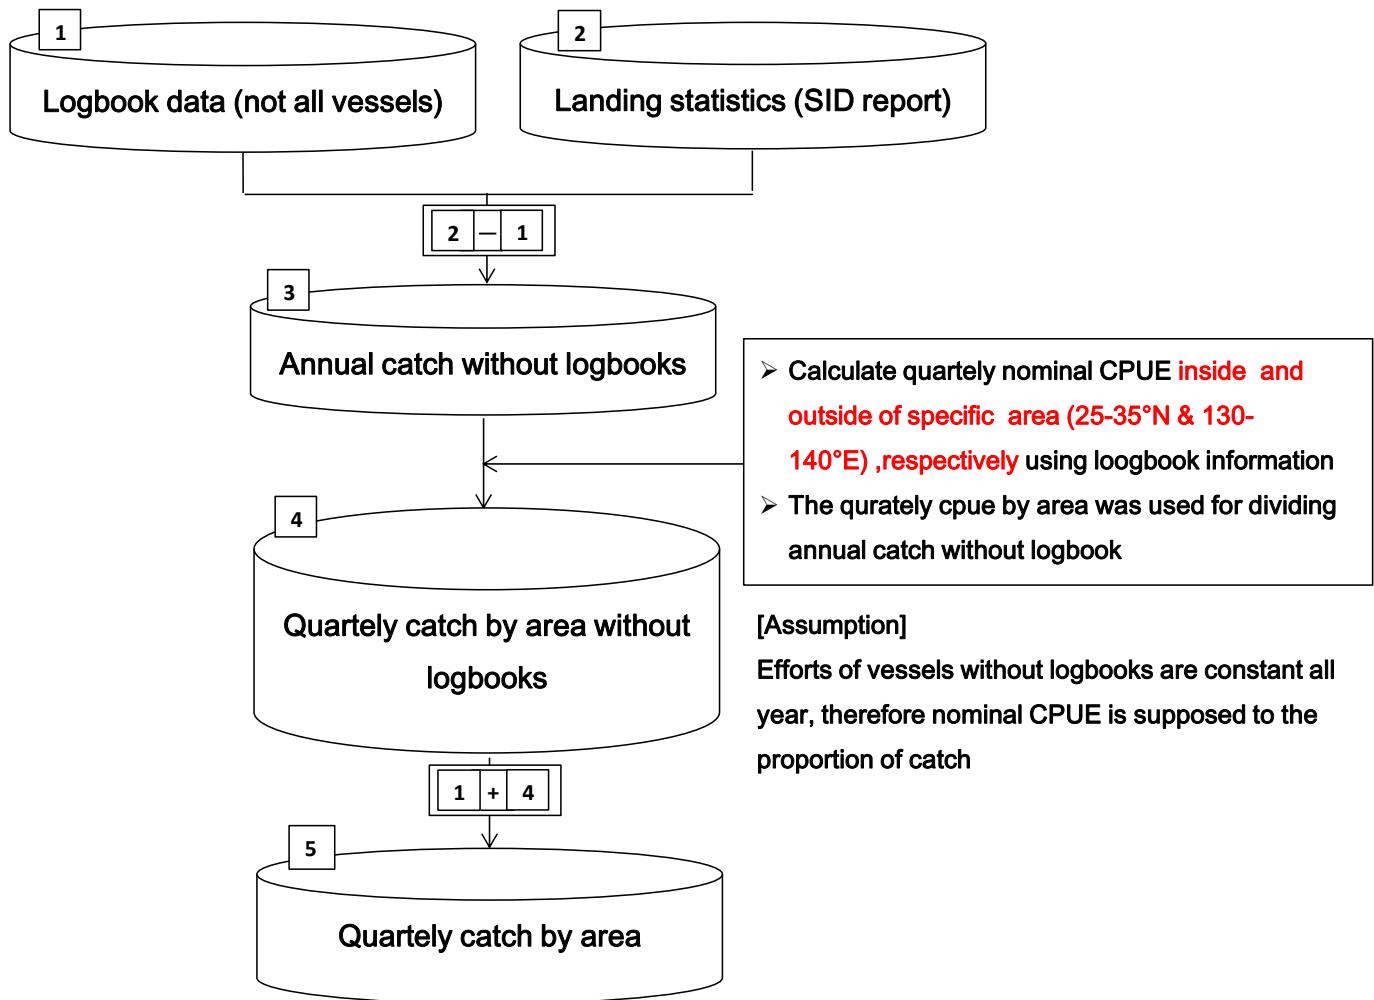

Fig. 1 Schematic diagram for creating JPN LL-small (fleet ID 3) and JPN LL-large (fleet ID 4) of Japanese coastal longline vessel. Red letters represent modification from previous method (Matsumoto et al 2013). The modification is due to the change of the fishery definition of the Japanese longline for albacore stock assessment.
