National Research Institute of Far Seas Fisheries 5-7-1, Orido, Shimizu-ku, Shizuoka 424-8633, Japan

March 2006

<sup>&</sup>lt;sup>1</sup>Working document prepared for the Sixth Meeting of the International Scientific Committee on Tuna and Tuna-like Species in the North Pacific Ocean (ISC), March 23-27, 2006, La Jolla, California, U.S.A. Document should not be cited without permission of the authors.

## National report of Japan

Koji Uosaki

National Research Institute of Far Seas Fisheries 5-7-1, Orido, Shimizu-ku, Shizuoka 424-8633, Japan

The total landing of tunas (excluding skipjack) caught by Japanese fisheries in the Pacific Ocean in 2003 was 187,000 metric ton (t) and the total landing of swordfish and billfishes was 17,000 t (Anonymous 2005). The landing of skipjack tuna was 322,000 t. Japanese tuna fisheries consist of the three major fisheries, i.e., longline, purse seine, pole-and-line, and other miscellaneous fisheries like troll, drift-net, set-net fisheries. These fisheries occupy more than 96 % of the total tuna catch of Japanese fisheries in recent years. This paper described the recent trend of the Japanese tuna fisheries in the Pacific Ocean and updated the statistics given in the previous national report for ISC5 (Ogura 2005). Also there was a brief description on Japanese research activities on tuna and tuna-like species in the Pacific Ocean in 2005 and early 2006.

## 1. Trends in fleet size

Table 1 shows the number of Japanese tuna boats actually engaged in fishing by type of fishery and vessel size class during 1980-2003 (Anonymous 1982-2005). The total number of longline vessels in 2003 was 1,390. The number of longline vessels of the largest size class (larger than 200 Gross Register Tonnage (GRT)) had been constant since the late 1960s. But according to the agreement at the FAO's international action plan on fishing capacity, it decreased 26% from 1998 to 2002. The number of the vessels for 20-49 GRT and 50-100 GRT showed sharp declines since the late 1980s.

Furthermore, this declining trend has been accelerated by the further slowdown of economic surrounding longline fishing (high fuel cost, low price of tuna, high supply of tuna from the foreign fisheries and low catches due to the decline of stock size) during the last few years. Many longline operators went bankrupt and many boats are now tied up at the home port.

The number of purse seine vessels shown in Table 1 includes only the vessel mainly targeting tunas. Although the total number of purse seine vessel was 53 in 2003, it was nearly 80% in the 1980s. The number of the smaller size (smaller than 200 GRT) purse seine vessels has decreased since the late 1980s, the larger vessels which operate mainly in the tropical waters do not show remarkable change in number.

In case of the pole-and-line fishery, the number of vessels larger than 20 GRT declined and was 145 corresponding to almost one third of those in the 1980s. The trend in the number of vessels smaller than 20 GRT is difficult to follow the long-term trend, but it may be also declining.

#### 2. Catch and effort trends of the major fisheries

Catch and effort data used in this paper are mostly based on the logbook data compiled by the National Research Institute of Far Seas Fisheries, Fisheries Research Agency (NRIFSF). The data source of catch and effort for the coastal longline fishery is derived from Statistics Department, Ministry of Agriculture, Forestry and Fishery (Anonymous 1982-2005).

## 2.1. Longline

Longline fisheries had been classified by vessel size into three categories in terms of the license of tuna fishery, i.e., coastal (vessels smaller than 20 GRT), offshore (20-120 GRT), and distant water (larger than 120 GRT) until 2001. Since the categorization on the license was changed in 2002, tuna vessels of 10–20 GRT operating outside the Japanese EEZ were categorized as offshore license. Latest available statistics are

provisional 2004 data for vessels larger than 20 GRT and are provisional 2003 data for the vessels less than 20 GRT.

Total days at sea of longline vessels smaller than 20 GRT have gradually increased since 1990 (Table 2). The effort in 2003 was 114,000 days which was a 50 % increase from that in 1980. Total catch of these vessels ranged from about 31,000 to 46,000 t in the last decade, and albacore is the largest portion corresponding to about a half of the total catch. Albacore catch has increased remarkably since 1993 and peaked at 25,000 t in 1999, but decreased to 16,000 t in 2003.

Total catch of longline vessels larger than 20 GRT (offshore and distant water fisheries) in the entire Pacific were 92,189 t in 2004 (Table 3). In the North Pacific (north of the equator), 110 million hooks were employed and 49,000 t of fish was caught in 2004. In the South Pacific, the fishing effort was 91 million hooks and the catch was 43,000 t in 2004. Bigeye has been the dominant species for both the North and the South Pacific and the catch in 2004 were nearly 27,000 t in the North Pacific and 19,000 t in the South Pacific.

The fishing effort of longline vessels larger than 20 GRT remained stable at around 200 million hooks in the North Pacific until the early 1990s, and then it has decreased up to the recent years. The similar situation of declining trend was seen in the South Pacific. Catch of bigeye, yellowfin and marlins in both the North and the South Pacific had been stable in the 1980s, but it shows the decreasing trend in the 1990s. Catches of Pacific bluefin tuna and albacore in the North Pacific showed some drops during the mid 1980s and a recovery in the early 1990s. A similar decline was also seen during the early 2000s. The catch of swordfish appears to be relatively stable.

The catch and effort by the distant water longline fishery are likely to decrease due to the economic circumstances (i.e. high fuel cost, low price of tuna). As large part of these boats have operated in the waters other than the North Pacific (more than 80%) such as south-east Pacific, Indian Ocean and Atlantic Ocean, the decline would be larger in those waters.

Annual distribution of fishing effort for longline vessels larger than 20 GRT in 2003 and 2004 were shown in Figure 1. The fishing grounds are located in east-west direction off Japan to Hawaii, equatorial area between 15 °S and 15 °N, off Australia and off Peru.

The length of albacore measured on board and at landing sites ranged from 60 to 120 cm in fork length (FL) (Figure 2). The length of bigeye and yellowfin had wider ranges approximately from 60 to 180 cm but fish larger than 100 cm formed a dominant part of the catch. The length of the swordfish measured ranged from 50 to 240 cm in eye-fork length.

## 2.2. Purse seine

There are two different types of purse seiners that target tunas in Japan, i.e., single and group purse seine fisheries. The group seiner consists of one net purse seiner (100-200 GRT) and one searching vessel and two carrier vessels, and operates in the temperate northwestern Pacific. New type of group seiner launched at March 2005 with one relatively large seiner (300 GRT) than typical size of the purse seiner and one carrier. The group purse seiner corresponds to the offshore purse seine fishery. The carrier holds fish in chilled water with ice. On the other hand, the single purse seiner (349-500 GRT) operates mainly in the tropical waters of the central and western Pacific, seasonally moves into the temperate waters. This type of purse seiner fishery is so called the distant water purse seine fishery.

Annual distribution of fishing effort (Figure 3) clearly showed that the fishing ground was well divided by latitude 20 °N into the northern temperate waters around Japan and the tropical waters. In the northern area, the number of sets was large at about 3,500-4,000 sets in the mid 1980s, decreased to about 2,000 sets during the late 1980s, then recovered in 1998 and remained at about 2,500-3,000 in recent years. In the southern area, the number of sets peaked at 7,000 set in 1984 then gradually decreased to 4,000 sets until the early 2000s (Table 4). Total catch in the northern area varied from 25,000 to 100,000 t. Skipjack catch in 1998 in this area was highest in the history, resulting in almost 100,000 t in total catch. Skipjack dominate in the catch in this area followed by yellowfin and Pacific bluefin, but the catch of each species has been fluctuated. In the southern area, number of

fishing effort increased rapidly until 1983 and then it was leveled off. Total catch in the southern area were stable at around 150,000 t or more after the mid 1980s. Skipjack occupies most of the catch followed by yellowfin and bigeye.

The length of skipjack caught by this fishery ranges from 30 to 70 cm in FL and bigeye ranges from 30 to 90 cm (Figure 4). Most of the catch of yellowfin is also in the range from 30 to 80cm but there are some fish in FL larger than 80 cm.

## 2.3. Pole-and-line

The pole-and-line fishery is composed of three different categories, i.e., coastal (smaller than 20 GRT), offshore (20-120 GRT) and distant water (lager than 120 GRT) vessels in terms of the license of this fishery. The pole-and-line fishery can be also categorized into large, middle, and small (sized) vessels which correspond to larger than 230 GRT, 20-230 GRT and less than 20 GRT in vessel size. This categorization is useful to discriminate between those fisheries in terms of fishing ground and fishing strategy.

The middle-sized vessels generally operate in near shore waters and their trip is within 10 days. Southern most fishing area for these vessels, in recent years, is near 15°N, but the important fishing ground is waters north of 20°N around Japan and adjacent areas. These vessels primarily fish for skipjack tuna from spring through autumn off Pacific side of Japan, and also take relatively small amount of albacore, yellowfin and bigeye tunas. They hold fish in cooled water and unload it as fresh fish. The activity of the small pole-and-line vessels is similar to that of the middle vessels but the area of fishing is limited to the coastal waters of Japan.

On the contrary, the large vessels operate much more offshore waters and their trips are for two or three months. Usually they primarily fish for albacore from summer through autumn season in the waters north of  $20^{\circ}$ N, and skipjack tuna in winter and spring in the waters south of  $20^{\circ}$ N. These vessels equip a brine freezer, in which fish caught is immediately stored into a tank filled with cooled brine (about 20% calcium chloride solution,  $-18^{\circ}$ C), and then unloads it as frozen fish.

As in the case of purse seine fishery, the fishing grounds of the pole-and-line fishery are separated by 20°N approximately (Figure 5). For both areas divided by 20°N, fishing effort has been decreasing, especially for the southern area. The fishing effort in 2004 was about 39 % of 1980 for the northern area and 20 % of 1980 for the southern area. Despite the substantial reduction of the fishing effort, the catch of skipjack and albacore in the northern area appears to be relatively stable. In the northern area, recent catches were variable, 50,000 to 110,000 t for skipjack, and 20,000 to 50,000 t for albacore. Skipjack and yellowfin catches in the southern area, by the large pole-and-line vessels, showed steep declines reflecting the concomitant reduction of the fishing effort.

Annual catch by the coastal pole-and-line fishery is 10,000 t or less and minor compared with that of the offshore and distant water pole-and-line fisheries.

The lengths of skipjack caught by this fishery are from 40 to 80 cm FL and albacore are from 50 to 100 cm with several clear modes (Figure 6).

### 2.4. Other fisheries

There are miscellaneous small scale fisheries which catch tunas and tuna-like species in the Japanese coastal waters. Among them, the largest catch is made by the troll fishery with annual catch in 2003 of about 6,505 t for tunas and 9,386 t for skipjack (Anonymous 2005).

The large mesh driftnet fishery historically expanded the fishing ground covering areas of the temperate north and South Pacific in the 1980s, was suspended in 1991 in the South Pacific and in the high seas of the North Pacific in 1992 due to UN resolution implemented for large scaled drift gillnet fishery in the high seas.

#### 2.5. Recent developments and trends of Pacific bluefin tuna, albacore and swordfish fisheries

Total catch of Pacific bluefin in Japan have been around 10,000 t after 2000 and preliminary estimate of total landing in 2005 was about 11,000 t, slightly increased from 10,421 t in 2004. Purse seine catch is the largest portion among gears and was 5,200 t in 2005 corresponding to the average level in the last 5 years. The longline

catch was 1,800 t and the troll catch was 1,800 t in 2005. Although those catches are the largest catch in the last 5 years, such increase dose not contribute to increase of the total Pacific bluefin catch.

In recent years, the troll fishery catches age 0 fish (20-30 cm in FL) of Pacific bluefin in summer in the Pacific and in autumn in the Sea of Japan. This fishery supplies fish not only for local market but also for the fattening. Catch amount used for fattening is likely to be around 20-40 t.

The catches of North Pacific albacore are mainly made by the longline and the pole-and-line fisheries. The pole-and-line catch was 34,727 t in 2004 (Table 5), and the catch in 2005 was about 17,000 t according to the information of albacore landing in major fishing ports, corresponding to about 50% in 2004 and the lowest level in the last decade. The longline catch was about 21,000 t in 2003 and 16,000 t in 2004 given as a preliminary estimate. One reason of the decreasing of the catch in 2004 was a lower catch rate in the first quarter in the waters off western Japan which is one of the most important fishing grounds for the coastal longline vessels.

Swordfish catch by the offshore and the distant water longliners in 2004 (6,510 t) in the North Pacific was 20% higher than that in 2003, which would at least partly be attributed to the increase of catch rate. Limited information from port samplers suggests that relatively good catch of swordfish was observed in the winter fishing season of 2005/2006.

## 3. Compilation of basic fisheries data

There are logbook systems for offshore and distant water longline, pole-and-line, and purse seine fisheries. From 1994, the logbook system has been also imposed on the coastal longline vessels (10-20 GRT) fishing both within and outside of the Japanese EEZ and these vessels were included in the offshore category at 2002. This means that all vessels larger than 20 GRT and from 2002 some longline vessels of 10-20 GRT are covered by logbook system and catch and effort data of these vessels are collected. Historical Category II data was compiled from those logbook data and submitted to the ISC Statistic Working Group in March 2006.

There are various small scale fisheries in the coastal waters of Japan such as troll and set net etc. which are not covered by the current logbook system, but their catches are covered by the landing statistics collected by the Statistics Department of the Ministry of Agriculture, Forestry and Fisheries (Anonymous 1982-2005). The Fishery Agency of Japan, in cooperation with the NRIFSF and local prefectural fisheries experimental stations, has run the nationwide port sampling project for catch, effort and size data for various fisheries at the major landing ports since the mid 1990s.

#### 4. Research activities

Researches on tunas and tuna-like species in the Pacific Ocean have been carried out by the NRIFSF for broad scientific areas of basic biology, behavior, and stock assessment. In addition, there are cooperative works with prefectural fisheries experimental stations and universities. Several cooperative studies are also on going with foreign countries including international organizations.

## 4.1. Research cruises in 2005 and 2006

There have been research cruises in 2005 fiscal year conducted by the Fisheries Agency of Japan and NRIFSF relating to tunas and billfish in the Pacific, in addition to the several short cruises for tagging.

A research cruise on juvenile tuna behavior around FADs was conducted by the R/V Shoyo-maru of the Fisheries Agency of Japan during June to September 2005 in the tropical central Pacific. In this cruise, ID pinger was used to simultaneously monitor the swimming depth of three species of tunas (bigeye, yellowfin and skipjack). Data were successfully obtained from 2 opportunities of 5 attempts, including 30 skipjack, 43 yellowfin and 32 bigeye individuals. Results showed that swimming depth in day time was deeper than at night for all species, and that of skipjack was shallower than those of yellowfin and bigeye. Three research cruises for tuna larvae and early juveniles were conducted by using a plankton net and a mid-water trawl gear.

bluefin and yellowfin larvae at the vicinity of Nansei-Islands during May to June 2005 to investigate survival process in the larval patches. The purpose of the other two cruises were to study distributions of larvae and early juvenile for bluefin in the Sea of Japan (August 2005), and skipjack in the tropical waters (February to March 2006).

A research cruise on behavior of adult albacore and billfishes was conducted also by the R/V Shoyo-maru during February to March 2006 in the western central Pacific using longline gear to obtain those fishes. Pinger tracking was done for two individuals of adult albacore and the tracking data were obtained for 12 hours and 24 hours each. In addition, archival tagging was done for 12 adult albacore.

To develop mitigation measures for reducing incidental mortality of sea turtles in longline fishery, experimental fishing operations were conducted in the western North Pacific from April to June, 2005 by using the R/V Kurosaki and RV Taikei No.2. Results of the experiment showed that circle hooks reduced deep hooking of loggerhead sea turtles compared to conventional tuna hooks and that the use of circle hooks had little effect on shark catch.

## 4.2. Tagging

The tagging using conventional tag has been conducted by research vessels as well as commercial vessels. Some of these are not dedicated tagging. In addition to the conventional tagging, tagging using the archival tag and archival popup tag has been conducted for tuna and tuna-like species.

For conventional tagging activity in 2005, 673 bigeye, 1,372 yellowfin and 2,355 skipjack were tagged and released. There were recovery reports of 8 bigeye, 19 yellowfin, and 57 skipjack. In addition to conventional tagging, 36 Pacific bluefin tuna, 40 albacore, 21 bigeye, and 2 yellowfin were tagged with an archival tag and released. Of those, 13 Pacific bluefin tuna and 5 bigeye were recovered. Furthermore, 4 blue marlin and 1 striped marlin were released with an archival pop-up tag in 2005. So far, tracking data was successfully obtained from 3 archival popup tags attached to blue marlin.

#### 4.3. Studies on biological parameter

Following is the studies on biological parameters recently carried out by the NRIFSF.

- The daily increment formation on otolith was validated for bigeye by the rearing experiment of fish injected with the OTC. Further detail analyses of the otoliths obtained are under going.
- Natural mortality of Pacific bluefin tuna, specific to age 0 was re-estimated from conventional tag-release-recapture data. The results suggest that the natural mortality of age 0 Pacific bluefin tuna currently in use (1.6) is reasonable with respect to the average M for age 0 fish.
- In order to determine size and age of maturity, histological observations were made for Pacific bluefin ovary samples collected from total 1,371 fishes caught by the purse seine fishery in the Sea of Japan in 2003 and 2004. Results indicated that 80 % of bluefin tuna at age 3 in the Sea of Japan were mature and 90 % of tuna at age 4 were mature.
- Length-weight relationships for albacore and Pacific bluefin was re-examined to obtain its parameters for stock assessments, particularly converting numbers at age into biomass at age in age structured models, using the fish measurement data in recent years. It is considered that further investigation is needed for both species.
- Stomach contents and gonads of blue marlins caught by coastal troll boats in the southwestern part of Ryukyu Islands were analyzed in collaboration with a university.

Table 3. Fishing effort (1,000 hooks) and catch in weight (t) by species for the vessels greater than 20 GRT of Japanese offshore longline fishery and distant water longline fishery in the Pacific. Data in 2004 is provisional. PBF: Pacific bluefin, SBF: southern bluefin, ALB: albacore, BET: bigeye, YFT: yellowfin, SWO: swordfish, MLS: striped marlin, BUM: blue marlin, BLM: Black marlin, SFA: sailfish and also includes spearfish

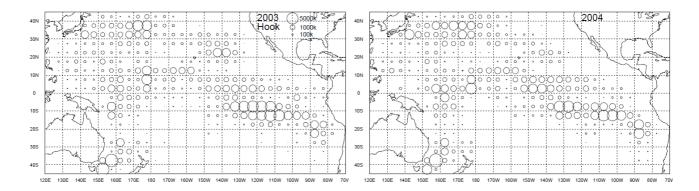

Figure 1. Distribution of fishing effort (Number of hooks) for the Japanese longline fishery (larger than 20 GRT vessels) in the Pacific. Left: 2003, right: 2004.

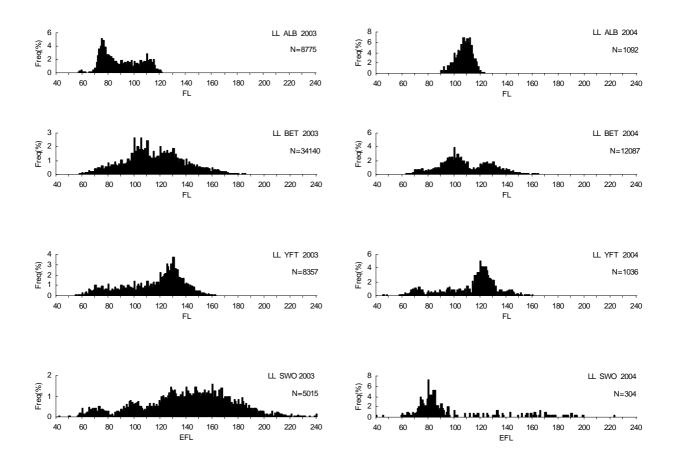

Figure 2. Annual length frequency distribution (simply summing up all measurements) for offshore and distant water longline caught albacore, bigeye, yellowfin, and swordfish in 2003 (left) and 2004 (right). Text in the right in each graph indicates gear, species, year, and the number of fish measured.

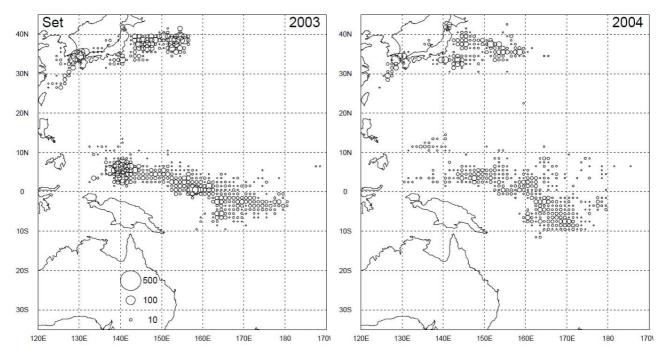

Figure 3. Distribution of fishing effort (number of sets) for the Japanese purse seine fishery in the Pacific. Left: 2003, right: 2004.

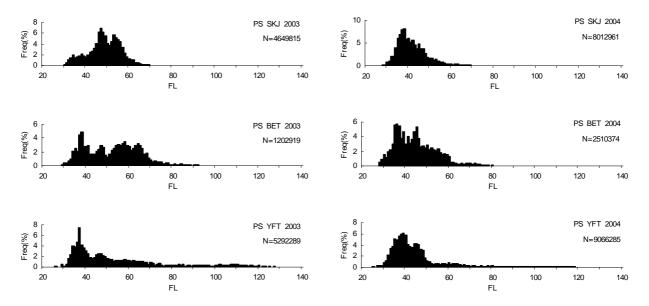

Figure 4. Annual length frequency distribution (so called catch-at-length) for distant water purse seine caught skipjack, bigeye, and yellowfin in 2003 (left) and 2004 (right). Text in the right in each graph indicates gear, species, year, and estimated number of fish caught by this fishery.

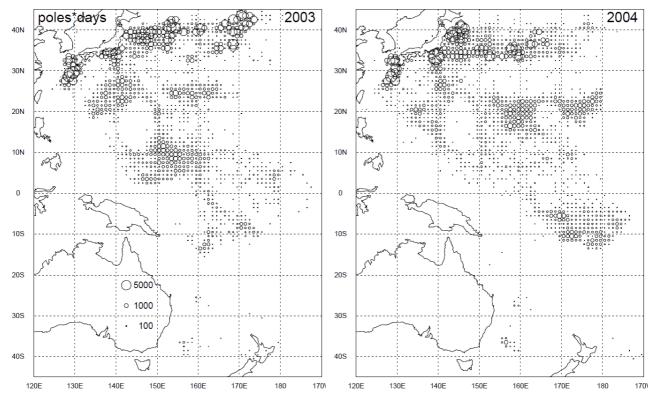

Figure 5. Distribution of fishing effort (number of poles days) of the Japanese pole-and-line fishery (larger than 20 GRT vessels) in the Pacific. Left: 2003, right: 2004.

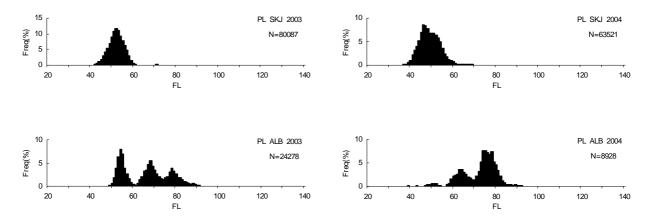

Figure 6. Annual length frequency distribution (simply summing up all measurements) for offshore and distant water pole-and-line caught skipjack and albacore in 2003 (left) and 2004 (right). Text in the right in each graph indicates gear, species, year, and the number of fish measured.
