

# REPORT OF THE TWENTY-FIRST MEETING OF THE INTERNATIONAL SCIENTIFIC COMMITTEE FOR TUNA AND TUNA-LIKE SPECIES IN THE NORTH PACIFIC OCEAN

PLENARY SESSION

12-15 and 19 July 2021 Virtual Meeting

#### **TABLE OF CONTENTS**

1		ODUCTION AND OPENING OF THE MEETING						
	1.1	Introduction						
	1.2	OPENING OF THE MEETING	11					
2	ADOP	TION OF AGENDA	12					
3	REPORT OF SPECIES WORKING GROUPS AND STOCK STATUS AND CONSERVATINFORMATION							
	3.1	North Pacific Albacore						
	3.1.1							
	3.1.2	North Pacific Albacore Stock Status and Conservation Information						
	3.1.3	Final Management Strategy Evaluation Report						
	3.2	PACIFIC BLUEFIN TUNA						
	3.2.1							
	3.2.2	Pacific Bluefin Tuna Stock Status and Conservation Information						
	3.3	BILLFISH	21					
	3.3.1	BILLWG Report and Review of Assignments	21					
	3.3.2	Pacific Blue Marlin Stock Assessment	23					
	3.3.3	Pacific Blue Marlin Stock Status and Conservation Information	25					
	3.3.4	Western and Central North Pacific Swordfish Stock Status and Conservation Information	1 34					
	3.3.5	Eastern Pacific Swordfish Stock Status and Conservation Information	36					
	3.3.6	Pacific Striped Marlin Stock Status and Conservation Information	38					
	3.4	Sharks	40					
	3.4.1	SHARKWG Report and Review of Assignments	40					
	3.4.2	Shortfin Mako Shark Indicator Analysis	41					
	3.4.3	Blue Shark Stock Status and Conservation Information						
	3.4.4	Shortfin Mako Shark Stock Status and Conservation Information	46					
	3.5	OBSERVER COMMENTS	47					
4	REVI	EW OF STATISTICS AND DATABASE ISSUES	48					
	4.1	STATWG REPORT	48					
	4.2	TOTAL CATCH TABLES	50					
5	REVI	EW OF MEETING SCHEDULE	51					
	5.1	TIME AND PLACE OF ISC22	51					
	5.2	TIME AND PLACE OF WORKING GROUP INTERSESSIONAL MEETINGS	51					
6	ADMI	NISTRATIVE MATTERS	54					
	6.1	ISC STOCK ASSESSMENT REVIEW PROPOSAL	54					
	6.2	Data Sharing Agreement	55					
	6.3	WORKING GROUP ELECTION RESULTS	55					
	6.4	ISC ORGANIZATIONAL CHART	56					
	6.5	OTHER MATTERS	58					
7	ADOP	TION OF REPORT	58					
8	CLOS	E OF MEETING	58					
9	CATC	CH TABLES	59					

#### LIST OF TABLES

Table 1. Reported catch (tonnes, mt) used in the stock assessment along with annual model-
averaged estimates of female spawning biomass (tonnes, mt), relative female spawning biomass
$(SSB/SSB_{MSY})$ , recruitment (thousands of age-0 fish), fishing mortality (average F, ages 1 – 10),
relative fishing mortality ( $F/F_{MSY}$ ), and spawning potential ratio (SPR) of Pacific blue marlin 28
Table 2. Estimates of biological reference points along with estimates of fishing mortality (F),
spawning stock biomass (SSB), recent average yield (C), and spawning potential ratio (SPR) of
Pacific blue marlin, derived from the assessment ensemble model, where "MSY" indicates
reference points based on maximum sustainable yield
Table 3. Projected median values of Pacific blue marlin spawning stock biomass (SSB, mt) and
catch (mt) under four constant fishing mortality rate (F) scenarios during 2020-2029
Table 4. Percent change of moving average of CPUE for four major fleets (S1, S3, S5 and S7)
used in the benchmark stock assessment in 2018. Moving averages were calculated using the
mean value of CPUE for five years. The percentage indicates the positive and negative change in
the moving average of CPUE between the start and end years from long term (all years with
data) and short term (the most recent 5 years). The last year of S5 was removed from the
calculation due to data from 2020 being preliminary. S1 US SS (US Hawaii longline shallow-
set), S3 TW LALL (Taiwan longline large-scale), S5 JP RTV (Japan research and training
vessels), and S7 MX OBS (Mexico observer for longline)
Table 5. North Pacific albacore ( <i>Thunnus alalunga</i> ) catches (in metric tons) by ISC member
fisheries, 1952-2018
Table 6. Pacific bluefin tuna ( <i>Thunnus orientialis</i> ) catches (in metric tons) by ISC member
fisheries, 1952-2018
Table 7. Annual catch of swordfish ( <i>Xiphias gladius</i> ) in metric tons for fisheries monitored by
ISC member countries for assessments of North Pacific Ocean stocks, 1951-2018
Table 8. Annual catch of striped marlin ( <i>Kajikia audax</i> ) in metric tons for fisheries monitored by
ISC member countries for assessments of North Pacific Ocean stocks, 1951-2018
Table 9. Retained catches (metric tons, whole weight) by ISC Member countries of blue marlin
(Makaira nigricans) by fishery in the North Pacific Ocean, north of the equator 1953-2020 67
Table 10. Retained catches (metric tons, whole weight) by ISC Member countries of blue sharks
( <i>Prionace glauca</i> ) by fishery in the North Pacific Ocean, north of the equator, 1985-2020 68
Table 11. Retained catches (metric tons, whole weight) by ISC Member countries of shortfin
mako sharks ( <i>Isurus oxyrhinchus</i> ) by fishery in the North Pacific Ocean, north of the equator,
1985-2020
1705 2020.
LIST OF FIGURES
Figure 1. Annual catch biomass (tonnes, mt) of Pacific blue marlin (Makaira nigricans) by
country for Japan, Chinese Taipei, the U.S.A., and all other countries during 1975-2019 30
Figure 2. Length-at-age for Pacific blue marlin from the old growth model (von-Bertalanffy
curve, black lines) and the new growth model (Richards curve, blue lines) by sex (females
diamonds, males circles) used in the 2021 assessment.

Figure 3. Time series of estimates of female spawning stock biomass over female spawning stock biomass at MSY (top left), fishing mortality over fishing mortality at MSY (top right), spawning stock biomass (center left), instantaneous fishing mortality (ages 1-10 year <sup>-1</sup> , center right), recruitment (age-0 fish, bottom left), and catch (bottom right) for Pacific blue marlin ( <i>Makaira nigricans</i> ) derived from the 2021 stock assessment model ensemble. Lines (or points for recruitment) indicate the median value estimated from the joint multivariate delta-lognormal estimation, shaded areas (or error bars for recruitment) indicate the 95% confidence intervals. Unweighted indicates that both models have equal weights in the ensemble

ANNEX 13	Report of the Albacore Working Group Workshop, 18–19-20, 24-25 May 2021
ANNEX 14	Report of the Statistics Working Group Workshop, 6-7 July 2021
ANNEX 15	Report of the Albacore Working Group Workshop, 31 Aug $-$ 3 and 8 Sep 2020 (Eastern Pacific) / $1-4$ , 9 Sep 2020 (Western Pacific)
ANNEX 16	Report of the Albacore Working Group Workshop, $1-4$ and $8$ Dec 2020 (Eastern Pacific) $/2-5$ and $9$ Dec 2020 (Western Pacific)

#### **ACRONYMS AND ABBERVIATIONS**

#### Names and FAO Codes of ISC Species of Interest in the North Pacific Ocean

FAO Code	Common English Name TUNAS	Scientific Name
ALB	Albacore	Thunnus alalunga
BET	Bigeye tuna	Thunnus obesus
PBF	Pacific Bluefin tuna	Thunnus orientalis
SKJ	Skipjack tuna	Katsuwonus pelamis
YFT	Yellowfin tuna	Thunnus albacares
	BILLFISHES	
BIL	Other billfish	Family Istiophoridae
BLM	Black marlin	Makaira indica
BUM	Blue marlin	Makaira nigricans
MLS	Striped marlin	Kajikia audax
SFA	Sailfish	Istiophorus platypterus
SSP	Shortbill spearfish	Tetrapturus angustirostris
SWO	Swordfish	Xiphias gladius
	SHARKS	
ALV	Common thresher shark	Alopias vulpinus
BSH	Blue shark	Prionace glauca
BTH	Bigeye thresher shark	Alopias superciliosus
FAL	Silky shark	Carcharhinus falciformis
LMA	Longfin mako	Isurus paucus
LMD	Salmon shark	Lamna ditropis
OCS	Oceanic whitetip shark	Carcharhinus longimanus
PSK	Crocodile shark	Pseudocarcharias kamonharai
PTH	Pelagic thresher shark	Alopias pelagicus
SMA	Shortfin mako shark	Isurus oxyrinchus
SPN	Hammerhead spp.	Sphyrna spp.

#### **ISC Working Groups**

Acronym	Name	Chair
ALBWG	Albacore Working Group	Sarah Hawkshaw (Canada)
BILLWG	Billfish Working Group	Hirotaka Ijima (Japan)
PBFWG	Pacific Bluefin Working Group	Shuya Nakatsuka (Japan)
SHARKWG	Shark Working Group	Mikihiko Kai (Japan)
STATWG	Statistics Working Group	Felipe Carvalho (U.S.A)

## REPORT OF THE TWENTY-FIRST MEETING OF THE INTERNATIONAL SCIENTIFIC COMMITTEE FOR TUNA AND TUNA-LIKE SPECIES IN THE NORTH PACIFIC OCEAN

#### PLENARY SESSION

12/13-15/16 and 19/20 July 2021

#### Highlights of the ISC21 Plenary Meeting

The 21st ISC Plenary, held as a virtual meeting, July 12-15 and 19, 2021 (Pacific Daylight Time) was attended by Members from Canada, Chinese Taipei, Japan, Republic of Korea, Mexico and the United States as well as the Inter-American Tropical Tuna Commission and Western and Central Pacific Fisheries Commission representatives. Observers from Monterey Bay Aguarium/Duke University, Pew Charitable Trusts, Western Fishboat Owners' Association, and the Western Pacific Fisheries Management Council, World Wildlife Fund-Japan, and Wild Oceans also attended the ISC21 Plenary session. The Plenary reviewed results, conclusions, new data, and updated analyses of the Billfish, Albacore, Shark, and Pacific Bluefin Tuna working groups. The Plenary endorsed the Pacific Blue Marlin (BUM) stock assessment and considers it to be the best available scientific information on this stock. Although reference points have not been established for the BUM stock, the stock is very likely (>90%) not overfished and overfishing is very likely (>90%) not occurring relative MSY-based reference points. An indicator analysis was conducted for North Pacific Shortfin Mako Shark (SMA) based on trends in catches and abundance indices supplemented by size frequency data because of the long period between benchmark stock assessments. The Plenary endorsed the conclusion that there were no obvious signs of shifts in abundance or fishery dynamics and the conclusion that a change in the date for the next benchmark stock assessment of SMA in 2024 was not warranted. The Plenary endorsed the BILLWG recommendation to expedite the next WCNPO MLS assessment for completion in 2022 and the responses prepared by the BILLWG to questions posed by WCPFC17 regarding discrepancies in catches of Western and Central Pacific Ocean Striped Marlin (MLS) stock. The Plenary revised the conservation information for WCNPO MLS with additional information related to updating the rebuilding plan with the most recent scientific information produced by the expedited benchmark assessment in 2022 and some remarks regarding the rebuilding target definition. The Plenary re-iterated stock status and conservation information provided at ISC20 for North Pacific Albacore (NPALB), Pacific Bluefin Tuna (PBF), WCNPO Swordfish (SWO), Eastern Pacific Ocean Swordfish (EPO SWO), Pacific Blue Marlin (BUM), North Pacific Blue Shark (BSH), and North Pacific Shortfin Mako Shark (SMA). The ISC work plan for 2021-22 includes benchmark stock assessments of MLS and BSH, an update assessment for PBF, advancing biological sampling for billfish and shark species, engaging the IATTC and WCPFC-NC on a PBF MSE process, reviewing the ISC Operations Manual to improve accountability and transparency, and continued implementation of enhancements to database and website management. Sarah Hawkshaw (CAN) was elected Chair of the ALBWG and Felipe Carvalho (USA) was elected Chair of the STATWG. Mikihiko Kai (JPN) and Michael Kinney (USA) were reelected to their second 3-yr term as Chair and Vice-Chair, respectively, of the SHARKWG. The next ISC Plenary will be hosted by the United States of America in Kona, Hawai'i, July 12-18, 2022.

#### 1 INTRODUCTION AND OPENING OF THE MEETING

#### 1.1 Introduction

The ISC was established in 1995 through an intergovernmental agreement between Japan and the United States (U.S.A.). Since its establishment and first meeting in 1996, the ISC has undergone a number of changes to its charter and name (from the Interim Scientific Committee to the International Scientific Committee) and has adopted a number of guidelines for its operations. The two main goals of the ISC are (1) to enhance scientific research and cooperation for conservation and rational utilization of the species of tuna and tuna-like fishes that inhabit the North Pacific Ocean during a part or all of their life cycle; and (2) to establish the scientific groundwork for the conservation and rational utilization of these species in this region. The ISC is made up of voting Members from coastal states and fishing entities of the region as well as coastal states and fishing entities with vessels fishing for highly migratory species in the region, and non-voting Members from relevant intergovernmental fishery and marine science organizations, recognized by all voting Members.

The ISC provides scientific advice on the stocks and fisheries of tuna and tuna-like species in the North Pacific Ocean to the Member governments and regional fisheries management organizations. Fishery data tabulated by ISC Members and peer-reviewed by the species and Statistics Working Group (STATWG) form the basis for research conducted by the ISC. Although some data for the most recent years are incomplete and provisional, the total catch of highly migratory species (HMS) by ISC Members estimated from available information is in excess of 500,000 metric tons (t) annually and dominated by the tropical tuna species. Catches of priority species by ISC Member countries in 2020 were 36,226 t of North Pacific albacore tuna (NPALB, *Thunnus alalunga*), 13,779 t of Pacific Bluefin tuna (PBF, *T. orientalis*), 8,508 t of North Pacific swordfish (SWO, *Xiphias gladius*), 2,443 t of North Pacific striped marlin (MLS, *Kajikia audax*), 4,703 t of Pacific blue marlin (BUM, *Makaira nigricans*), 1,259 t of North Pacific shortfin mako shark (SMA, *Isurus oxyrinchus*) and 22,415 t of North Pacific blue shark (BSH, *Prionace glauca*). <sup>1</sup> The total estimated catch of these seven species is 89,333 t, or approximately 80% of the 2020 total estimated catch of 112,186 t. Annual catches of priority stocks throughout their ranges reported by ISC Members are shown in Table 5 through Table 11.

#### 1.2 Opening of the Meeting

The Twenty-first Plenary session of the ISC (ISC21) was convened as a virtual meeting, at 18:00 on 12 July 2021 by the ISC Chair, J. Holmes.<sup>2</sup> A roll call confirmed the presence of delegates from Canada, Chinese-Taipei, Japan, Mexico, Republic of Korea, and U.S.A. (ISC/21/ANNEX/01). Non-voting members from the Secretariat of the Pacific Community (SPC), the Western and Central Pacific Fisheries Commission (WCPFC) and the Inter-American Tropical Tuna Commission (IATTC) were also present. Representatives from Monterey Bay

<sup>&</sup>lt;sup>1</sup> FAO three-letter species codes are used throughout this report interchangeably with common names.

<sup>&</sup>lt;sup>2</sup> Time given as Pacific Daylight Time (UTC -7) or for other members 09:00 China Standard Time (UTC +8), 10:00 Japan/Korea Standard Time (UTC +9) (July 13), or 15:00 Hawai'i Standard Time (UTC -10).

Aquarium/Duke University, Pew Charitable Trusts, Western Fishboat Owners' Association, and the Western Pacific Fisheries Management Council, World Wildlife Fund-Japan, and Wild Oceans were present as observers.

ISC Member China, as well as the non-voting Members, the Fisheries and Agriculture Organization of the United Nations (FAO) and North Pacific Marine Science Organization (PICES), while extended an invitation, did not attend the Plenary.

#### 2 ADOPTION OF AGENDA

The proposed agenda for the session (ISC/21/ANNEX/02) was considered and adopted. C. Dahl was assigned lead rapporteur duties. A list of meeting documents is contained in ISC/21/ANNEX/03.

Due to the constraints of the online format, national reports were not presented during Plenary. Written reports are compiled as documents ISC/21/PLENARY/04 through ISC/21/PLENARY/09.

A list of common abbreviations and acronyms used by the ISC is provided in the preface to this report.

## 3 REPORT OF SPECIES WORKING GROUPS AND STOCK STATUS AND CONSERVATION INFORMATION

#### 3.1 North Pacific Albacore

#### 3.1.1 ALBWG Working Group Report and Review of Assignments

S. Teo reported on the activities of the ALBWG over the past year (ISC/21/ANNEX/13/15/16). There were three ALBWG workshops focusing on the NPALB management strategy evaluation (MSE), as well as three MSE workshops for managers and stakeholders. All workshops were held online due to COVID-19 related travel restrictions. The first ALBWG management strategy evaluation (MSE) workshop was held during 31 August – 3 September, and 8 September 2020 (EPO dates) to: 1) review the progress of the MSE after the initial round of the MSE; 2) asses if any additional modifications to the MSE framework or additional analyses were required; and 3) provide feedback on presentation of results. The second ALBWG MSE workshop was held during 1 – 4, and 8 December 2020 (EPO dates) to: 1) review the progress of the MSE after the first MSE workshop in September; 2) draft the final report of the NPALB MSE; and 3) organize the MSE workshops for managers and stakeholders in 2021. The ALBWG organized three separate MSE workshops for managers and stakeholders to alleviate issues with different languages and time zones (Japan: 17 - 19 March 2021; Canada and U.S.: 22 - 25 March 2021; and Taiwan: 7 - 8 April 2021). The objectives of these workshops were to: 1) help managers and stakeholders understand the MSE results; and 2) provide feedback to the ALBWG on the presentation of results. The third ALBWG MSE workshop was held during 18 – 19, and 24 May 2021 (EPO dates) to: 1) review feedback from the NPALB MSE workshops with managers and stakeholders; 2) propose and review response to the feedback; and 3) election if new ALBWG Chair. The ALBWG supported the main results of the MSE and agreed with the ISC Chair that

the MSE results need to be assimilated by managers and stakeholders before further iterations of the MSE.

The ALBWG proposed the following 2021 – 2022 meeting schedule:

Date	Location/Method	Task/Event
11 – 19 Aug 2021	Online	WCPFC SC17. Report of MSE results and recorded video presentation provided for posting on SC17 online discussion forum website. Authors are responsible for any text communications.
5 – 7 Oct 2021	Online	WCPFC NC17. Format of presentation of MSE results to be determined.
Early 2022	Yokohama, Japan	ALBWG: Workshop for Assessment Improvements

#### **Discussion**

The Plenary endorsed the ALBWG's proposed work plan.

## 3.1.2 North Pacific Albacore Stock Status and Conservation Information

The ALBWG recommended carrying forward the stock status and conservation information from ISC20, because there is no new stock assessment or other substantive information that would suggest a need to change these determinations. The Plenary endorsed this recommendation.

The Plenary discussed whether the adoption of additional biological reference points for the stock, based on the results of the management strategy evaluation (see Section 3.1.3), could potentially affect this stock status and conservation information. The ALBWG Vice Chair suggested that the WG could consider the implications of any newly adopted reference points at its proposed meeting in early 2022 and bring forward recommendations to ISC22.

In response to a question about the relationship between "current" fishing intensity (F<sub>2015-2017</sub>) and the conservation measures adopted by the WCPFC and IATTC that limit fishing effort to the average of the 2002-2004 level (IATTC Resolution C-05-02 only specifies that the 'current' level of fishing is not to be exceeded but the 'current' in the Resolution is interpreted as the average of 2002-2004), it was noted that current fishing intensity would correspond to fishing effort below the 2002-2004 level.

#### **Stock Status and Conservation Information**

The Plenary reviewed and agreed to forward the stock status and conservation information adopted at ISC20 (see Section 3.1.2 pp. 5-15 in the ISC20 Plenary Report) unchanged, except for the omission of accompanying figures and tables.

#### **Stock Status**

Estimated total stock biomass (males and female at age-1+) declines at the beginning of the time series until 2000, after which biomass becomes relatively stable. Estimated female SSB exhibits a similar population trend, with an initial decline until 2003 followed by fluctuations without a clear trend through 2018. However, estimated recruitment reached historical lows in 2014 ( $\sim$ 125 million fish; 95% CI: 69 – 180 million fish) and 2015 ( $\sim$ 113 million fish; 95% CI: 56 – 170 million fish), which may have contributed to relatively low catches of fisheries catching juvenile albacore in recent years. It is currently unclear whether recruitment improved after 2015 because recruitment during the terminal years of the assessment (2016 – 2018) have large uncertainties.

The estimated average SPR (spawners per recruit relative to the unfished population) during 2015 - 2017 is 0.50 (95% CI: 0.36 - 0.64), which corresponds to a moderate fishing intensity (i.e., 1-SPR = 0.50). Instantaneous fishing mortality at age (F-at-age) is similar in both sexes through age-5, peaking at age-4 and declining to a low at age-6, after which males experience higher F-at-age than females up to age 12. Juvenile albacore aged 2 to 4 years comprised approximately 70% of the annual catch between 1994 and 2018. The dominance of juveniles is also reflected in the larger impact of surface fisheries (primarily troll, pole-and-line), which remove juvenile fish, relative to longline fisheries, which primarily remove adult fish).

The WCPFC -NC, which manages this stock in conjunction with the IATTC, adopted a biomass-based LRP in 2014 of 20% of the current spawning stock biomass when F=0 (20%SSB<sub>current, F=0</sub>). The 20%SSB<sub>current, F=0</sub> LRP is based on dynamic biomass and fluctuates depending on changes in recruitment. This LRP is calculated for NPALB as 20% of the unfished dynamic female spawning biomass in the terminal year of this assessment (i.e., 2018) (WCPFC-NC13 Summary Report). However, neither the IATTC nor the WCFPC-NC have adopted F-based reference points for the NPALB stock.

Stock status is depicted in relation to the LRP ( $20\%SSB_{current, F=0}$ ) for the stock and the equivalent fishing intensity ( $F_{20\%}$ ; calculated as 1-SPR<sub>20%</sub>). Fishing intensity ( $F_{current, F=0}$ ) is a measure of fishing mortality expressed as the decline in the proportion of the spawning biomass produced by each recruit relative to the unfished state. For example, a fishing intensity of 0.8 will result in an SSB of approximately 20% of SSB<sub>0</sub> over the long run. Fishing intensity is considered a proxy of fishing mortality.

The Kobe plot shows that the estimated female SSB has never fallen below the LRP since 1994, albeit with large uncertainty in the terminal year (2018) estimates. Even when alternative hypotheses about key model uncertainties such as growth were evaluated, the point estimate of female SSB in 2018 (SSB<sub>2018</sub>) did not fall below the LRP, although the risk increases with the more extreme assumption. SSB<sub>2018</sub> was estimated to be 58,858 t (95% CI: 27,751 – 89,966 t) and 2.30 (95% CI: 1.49 – 3.11) times greater than the estimated LRP t of 25,573 t (95% CI: 19,150 – 31,997 t). Current fishing intensity,  $F_{2015-2017}$  (0.50; 95% CI: 0.36 – 0.64; calculated as 1-SPR<sub>2015-2017</sub>) , was at or lower than all seven potential F-based reference points identified for the NPALB stock.

Based on these findings, the following information on the status of the north Pacific albacore stock is provided:

- 1. The stock is likely not overfished relative to the limit reference point adopted by the Western and Central Pacific Fisheries Commission (20%SSB<sub>current, F=0</sub>), and
- 2. No F-based reference points have been adopted to evaluate overfishing. Stock status was evaluated against seven potential reference points. Current fishing intensity (F2015-2017) is likely at or below all seven potential reference points.

#### **Conservation Information**

Two harvest scenarios were projected to evaluate impacts on future female SSB: F constant at the 2015-2017 rate over 10 years ( $F_{2015-2017}$ ) and constant catch<sup>3</sup> (average of 2013-2017 = 69,354 t) over 10 years. Median female SSB is expected to increase to 62,873 t (95% CI: 45,123 - 80,622 t) by 2028, with a low probability of being below the LRP by 2028, if fishing intensity remains at the 2015-2017 level. If future catch is held constant at 69,354 t, then the female SSB is expected to increase to 66,313 t (95% CI: 33,463 - 99,164 t) by 2028 and the probability that female SSB will be below the LRP by 2028 is slightly higher than the constant F scenario. Although the projections appear to underestimate the future uncertainty in female SSB trends, the probability of breaching the LRP in the future is likely small if the future fishing intensity is around current levels.

Based on these findings, the following information is provided:

- 1. If a constant fishing intensity (F<sub>2015-2017</sub>) is applied to the stock, then median female spawning biomass is expected to increase to 62,873 t and there will be a low probability of falling below the limit reference point established by the WCPFC by 2028.
- 2. If a constant average catch ( $C_{2013-2017} = 69,354$  t) is removed from the stock in the future, then the median female spawning biomass is also expected to increase to 66,313 t and the probability that SSB falls below the LRP by 2028 will be slightly higher than the constant fishing intensity scenario.

#### 3.1.3 Final Management Strategy Evaluation Report

The ALBWG conducted an MSE for NPALB to examine the performance of alternative harvest control rules (HCRs) and associated reference points for the stock. Performance was evaluated based on management objectives pre-agreed upon with managers and stakeholders in a series of workshops.

Management objectives and performance metrics were finalized in October 2017, at the 3<sup>rd</sup> ISC NPALB MSE Workshop in Vancouver, Canada, where candidate reference points and HCRs for testing were also agreed upon. An initial set of MSE results was presented to managers and

<sup>3</sup> It should be noted that the constant catch scenario is inconsistent with current management approaches for north Pacific albacore tuna adopted by the Inter-American Tropical Tuna Commission (IATTC) and the Western and Central Pacific Fisheries Commission (WCPFC).

stakeholders during the 4<sup>th</sup> ISC NPALB MSE Workshop in February 2019 in Yokohama, Japan. Managers and stakeholders at the 4<sup>th</sup> MSE Workshop recommended removal from further consideration of two candidate harvest strategies and target reference points (TRPs) and assessment of performance of additional candidate HCRs focused on the best performing TRPs of F<sub>40%</sub> and F<sub>50%</sub>.

The results presented here focus on evaluation of the 16 HCRs and associated reference points proposed at the 4<sup>th</sup> MSE Workshop. The MSE tested HCR performance under total allowable catch (TAC) control and mixed control management procedures. Under the mixed control procedure, longline fleets catching NPALB incidentally are subject to a TAC, while the surface fleets targeting NPALB are controlled by total allowable effort (TAE). Mixed control maintained higher and less variable stock biomass than TAC control because the catches of surface fleets under effort control responded quickly to changes in biomass and their catch levels were not impacted by assessment errors in biomass estimates.

Because the NPALB stock is in good condition – even when considering the range of uncertainties in stock productivity; recruitment variability; availability to the EPO surface fleet; and observation, assessment, and implementation error – SSB rarely fell below the WCPFC's adopted LRP of 20% unfished dynamic spawning stock biomass (20%SSB<sub>current, F=0</sub>). This was true across the range of the candidate HCRs under both TAC and mixed control management procedures across all the reference stock productivity scenarios that were tested.

Under mixed control, there was a tradeoff between the odds of biomass being above the LRP and catch-related performance metrics. Under TAC control, the tradeoff between fishing intensity and catch variability led to the comparable odds of catch being above the historical average with both the  $F_{50\%}$  and  $F_{40\%}$  TRP families of HCRs.

Both mixed and TAC control were able to maintain the stock above the LRP with high probability (>0.8) even with increasing catches from an unknown, unmanaged fleet. This result occurred because the estimation model (the simulated stock assessment) correctly detects the decrease in biomass from the abundance indices and composition data despite observation error. As the TAC and TAE of the managed fleets are dependent on stock biomass, they are reduced over time and catches of the managed fleets diminish. Thus, maintenance of stock biomass comes at the cost of decreased catches for the managed fleets.

#### **Discussion**

The Plenary endorsed the MSE results, reiterating that no additional work is anticipated at this time.

The Plenary discussed the future validity of MSE results if a new benchmark stock assessment changes our understanding of stock status. The MSE evaluated management procedures across a wide range of operating models consolidated into four productivity scenarios. This approach should make the results robust in the face of changes in stock status. However, if assessment results suggest conditions outside the evaluated range, the MSE may need to be revisited. Otherwise, in presentations to managers it should be emphasized that no further iterations of the MSE results is planned at present.

It was noted that the recruitment scenarios used for MSE projections were not explicitly based on potential changes in environmental conditions, but the historical time series upon which they were based exhibits some year-to-year autocorrelation, suggesting environmental conditions that propagate across several years.

It was clarified that the ALBWG developed additional catch-related performance metrics by subsetting years within the 1981-2010 times series based on stakeholder recommendations.

It was noted that the robustness of management procedures under the scenario of undetected catch by a "ghost fleet" is a result of the simulated stock assessments interpreting changes in the abundance index and composition data as a reduction in spawning biomass resulting from a drop in recruitment. Corresponding controls are imposed on the managed fleets, which are thus "paying the price" for the catch of unmanaged fleets.

The upcoming presentation of the MSE in regional fishery management forums was discussed at length. Finding the right balance between technical detail, clarity, and conciseness is challenging. A more technical presentation would be appropriate for an audience such as the WCPFC Scientific Committee while focusing on the MSE results with less technical detail would be better for fishery managers participating in the next Northern Committee meeting. Providing materials in advance, including a prerecorded presentation, would likely enhance uptake by managers. The ISC Chair will work with the Northern Committee Chair to ensure necessary time is allocated on its meeting agenda and that other arrangements discussed by the Plenary are accommodated.

#### 3.2 Pacific Bluefin Tuna

#### 3.2.1 PBFWG Report and Review of Assignments

S. Nakatsuka, PBFWG Chair, reported the activities of WG for the past year (ISC/21/ANNEX/12). The WG did not conduct a PBF stock assessment last year and held one intersessional meeting in April 2021. In the intersessional meeting, the WG reviewed the latest catch data and noted catch increases by several members that were within the catch limits of the CMMs currently in force (WCPFC CMM 2020-02; IATTC Resolution C-20-02). The WG also reviewed abundance indices. The longline indices from Japan and Chinese Taipei, from which SSB abundance is inferred, showed a strong increase, supporting the continuing recovery trend of the stock. As to the recruitment index that has been used in the assessment, the WG is concerned with the impact of stricter management controls implemented in 2017 on data availability. Because these controls affect fishery behavior, the WG believes that the current index may be negatively biased after the 2016 fishing year and thus the index from subsequent years should not be included in future stock assessments. This bias is related to management measures in Japan encouraging the voluntary release of young PBF, which are not captured in the sales slip records (landings) that are the data source for this index. The WG will consider options for the inclusion of an appropriate recruitment index for the next stock assessment. The WG further noted that the terminal year (2018 fishing year) recruitment estimate was low in the last assessment, which was primarily informed by the Japanese troll recruitment index that is likely to be negatively biased. However, the effect of this issue on the stock status or conservation information is considered minimal, because the assessment and projections take

into account the high uncertainty of recruitment estimates. The WG concluded that there is no new information that necessitates revisions to the 2020 ISC Stock Status and Conservation Information for PBF.

The WG also reviewed the model structure of the current stock assessment and developed a basic framework for the updated stock assessment scheduled for completion in 2022. The WG also discussed how to proceed with a PBF MSE. One of the main benefits of an MSE is to account for data uncertainties. The WG concluded that given the high quality of the PBF assessment and lack of data inconsistencies, that is the catch data explained indices with good contrast, the need for a full MSE analysis is diminished. Therefore, the WG discussed using an ensemble approach rather than MSE to evaluate harvest strategies based on the 2020 stock assessment. However, if uncertainty cannot be captured in the ensemble approach, an MSE with a feedback loop may be needed. The WG agreed to discuss this issue further in fall 2021, based on the preliminary results from the ensemble model. In addition, the WG discussed the current status of close-kin mark recapture (CKMR) research on PBF. Members reported on their domestic research activities related to CKMR, but several members noted difficulties with continuing domestic CKMR research, because of the lack of a clear workplan endorsed by the ISC. WG members agreed to continue their domestic CKMR projects as they see fit.

The WC	- f-11	1-1 f +:		
The WG proposed th	e tollowing sche	aute of meetings	s and deadlines as	part of its workplan.

Date	Topic
November 2021	Data preparation workshop, including MSE
	progress review (Webinar);
December 31, 2021	Data submission for Catch and Size
	composition data, and preliminary results for
	the abundance indices
January 31, 2022	Data submission for the abundance indices
Early March 2022	Assessment meeting (format TBD)
April 1st, 2022	Submit the executive summary of the stock
	assessment report to the ISC chair for his
	review

#### **Discussion**

The Plenary discussed the barriers to progress on the PBF CKMR research agenda. Effective collaboration has been stymied by limitations of domestic capacity in the necessary analytical techniques and the reluctance to share confidential information on genetic markers in the interest of further developing such capacity. As a result, lack of coordination of research methods, such as which genetic markers to use, threatens the international research program. Overall, the lack of a coherent research plan agreed to by the Plenary has been the main contributor to these impediments. The Plenary asked the PBFWG to report back to the Plenary in 2022 on the need for CKMR to improve the accuracy and reliability of future stock assessments. Based on that advice, the Plenary may decide on any further development of an ISC sponsored CKMR research program.

The Plenary discussed progress on the MSE and its importance for strategic decision making. A major impediment to the development of the MSE has been the lack of input from managers on management objectives and alternatives management procedures (BRPs, HCRs, management controls, etc.) despite PBFWG efforts. Concern was expressed regarding the capacity needed to conduct an MSE, given the assessment workload and the fact that the WCPFC and IATTC have not provided clear direction and guidance on the MSE process. It was agreed that the ISC Chair and the PBFWG Chair would draft a document describing these concerns and submit it for discussion at the Sixth Meeting of the IATTC-WCPFC NC Joint Working Group on the Management of Pacific Bluefin Tuna scheduled for July 27-29, 2021.

Issues with the current recruitment indices were discussed. As noted by the PBFWG, the Japanese troll index may be negatively biased since 2017 because of management controls affecting landings, the data source for this index. Japan has also developed an index based on electronic monitoring of troll vessels that is expected to be less affected by these changes in behavior because it is not landings based, but this index has a much shorter time series. The PBFWG Chair noted that the problems with the current Japanese troll index and the implications of switching to an alternative index will be further discussed at the WG's planned November 2021 meeting.

The selection of the Taiwanese longline index from the results of different statistical methods was also discussed. A delta-generalized linear mix model (delta-GLMM) has heretofore been used while a vector-auto-regressive spatiotemporal (VAST) model was tested since 2018. The two methods produce similar results, but the VAST model approach has the disadvantage that it can only be applied to a shorter historical time period with detailed geo-location information in the data.

The Plenary endorsed the PBFWG's proposed workplan.

#### 3.2.2 Pacific Bluefin Tuna Stock Status and Conservation Information

The Plenary reviewed and agreed to forward the stock status and conservation information adopted at ISC20 (see Section 3.2.2, pp. 17-31 in the <u>ISC20 Plenary Report</u>) unchanged, except for the omission of accompanying figures and tables and clarifying modifications.

#### **Stock Status**

The WCPFC and IATTC adopted an initial rebuilding biomass target (the median SSB estimated for the period from 1952 through 2014) and a second rebuilding biomass target (20%SSB<sub>F=0</sub> under average recruitment), without specifying a fishing mortality reference level. The 2020 assessment estimated the initial rebuilding biomass target (SSB<sub>MED1952-2014</sub>) to be 6.4%SSB<sub>F=0</sub> and the corresponding fishing mortality expressed as  $F_{6.4\%SPR}$ . The Kobe plot shows that the point estimate of the SSB<sub>2018</sub> was 4.5%SSB<sub>F=0</sub> and the recent (2016-2018) fishing mortality corresponds to  $F_{14\%SPR}$ . Although no reference points have been adopted to evaluate the status of PBF, an evaluation of stock status against some common reference points shows that the stock is overfished relative to biomass-based limit reference points adopted for other species in WCPFC (20%SSB<sub>F=0</sub>) and fishing mortality has declined but not reached the level corresponding to that reference point ( $F_{20\%SPR}$ ).

The PBF spawning stock biomass (SSB) has gradually increased in the last 8 years (2011-2018). Young fish (age 0-2) shows a more rapid increase in recent years). These changes in biomass coincide with a decline in fishing mortality over the last decade. Based on these findings, the following information on the status of the Pacific Bluefin tuna stock is provided:

- 1. The latest (2018) SSB is estimated to be 4.5% of SSB<sub>F=0</sub>, which is an increase from 4.0% estimated for 2016 (the terminal year in the previous assessment). No biomass-based limit or target reference points have been adopted for PBF. However, the PBF stock is overfished relative to the potential biomass-based reference points (SSB<sub>MED</sub> and 20%SSB<sub>F=0</sub>) adopted for other tuna species by the IATTC and WCPFC.
- 2. The recent (2016-2018) F%SPR is estimated to produce 14%SPR. Although no fishing mortality-based limit or target reference points have been adopted for PBF by the IATTC and WCPFC, recent fishing mortality is above the level producing 20%SPR. However, the stock is subject to rebuilding measures including catch limits and the capacity of the stock to rebuild is not compromised by this fishing mortality, as shown by the projection results.

#### **Conservation Information**

After the steady decline in SSB from 1995 to the historically low level in 2010, the PBF stock has started recovering slowly, consistent with the management measures implemented in 2014-2015. The spawning stock biomass in 2018 was below the two biomass rebuilding targets adopted by the WCPFC while the 2016-18 fishing mortality (F<sub>%SPR</sub>) has reduced to a level producing 14%SPR.

The projection results based on the base-case model under several harvest and recruitment scenarios and time schedules requested by the RFMOs are in the ISC20 Plenary Report. The projection results show that PBF SSB recovers to the biomass-based rebuilding targets due to reduced fishing mortality by applying catch limits as the stock increases. In most of the scenarios, the SSB biomass is projected to recover to the initial rebuilding target (SSB<sub>MED</sub>) in the 2020 fishing year (April of 2021) with a probability above the 60% level prescribed in the WCPFC CMM 2019-02.

A Kobe chart and impacts by fleets estimated from future projections under the current management scheme are provided for information. Because the projections include catch limits, fishing mortality ( $F_{x\%}$ ) is expected to decline, i.e., SPR will increase, as biomass increases. Further stratification of future impacts is possible if the allocation of increased catch limits among fleets/countries is specified.

Based on these comments, the following conservation information is provided:

- 1. Under all examined scenarios the initial goal of WCPFC and IATTC, rebuilding to SSB<sub>MED</sub> by 2024 with at least 60% probability, is reached and the risk of SSB falling below historical lowest observed SSB at least once in 10 years is negligible.
- 2. The projection results assume that the CMMs are fully implemented and are based on certain biological and other assumptions. For example, the future projection results do not contain assumptions about discard mortality. Although the impact of

- discards on SSB is small compared to other fisheries, discards should be considered in the harvest scenarios.
- 3. Given the low SSB, the uncertainty in future recruitment, and the influence recruitment has on stock biomass, monitoring recruitment and SSB should continue so that the recruitment level can be understood in a timely manner.

#### 3.3 Billfish

#### 3.3.1 BILLWG Report and Review of Assignments

H. Ijima, Chair of the BILLWG, outlined four WG meetings held in 2020 and 2021.

In the 3-4 and 13 November 2020 biological research workshop, the number of samples for each length bin was determined based on the analysis of length composition data from Japan, Chinese Taipei, and the United States. The BILLWG also established a standard sampling methodology for billfish species. The workshop also addressed the use of the updated growth curve for BUM used in the stock assessment. The BILLWG updated the BUM growth curve based on new research; however, the BILLWG decided to build the SS3 model using both the old growth curve and the new growth curve and to adopt the growth curve exhibiting better model diagnosis results as the base case model.

At its 6-7, 10 and 13 November 2020 data preparation workshop the WG agreed on the input data and the model settings for conducting a benchmark stock assessment for BUM using Stock Synthesis 3.

At its 9-11 and 15 March 2021 intersessional meeting, in addition to reviewing progress on the BUM stock assessment, the WG also prepared a response to three questions posed by WCPFC 17 about the status of the WCNPO MLS stock. To formulate the WCNPO MLS stock rebuilding plan, the WG proposed, first, to conduct the MLS stock assessment in 2022 and update the rebuilding plan accordingly. The next SWO assessment would be delayed to 2023 to accommodate this work. The IATTC has proposed a new stock boundary dividing WCNPO and EPO SWO stocks. In consultation with SPC-OFP scientists, the WG agreed to consider this new stock boundary.

While WCPFC-NC14 requested that the BILLWG prepare a rebuilding plan for WCNPO MLS, the WG needs clarification on the rebuilding target,  $20\%SSB_{F=0}$ . It is not clear whether the rebuilding target is based on equilibrium  $SSB_0$  or whether dynamic  $SSB_0$  is required. If the rebuilding target is defined with a dynamic  $SSB_0$ , then the WG requests that the WCPFC-NC specify the target year for rebuilding.

WCPFC17 requested that the ISC address the three issues arising from the most recent WCNPO MLS stock assessment. The BILLWG recommended responses are summarized for each of these requests below. More detail is provided in ISC/21/ANNEX/08:

1. Examine differences between ISC stock assessment catch estimates by CCM and WCPFC catch estimates, and work with the Scientific Services Provider to provide an assessment of the shortcomings.

The BILLWG, which includes members from the Scientific Services Provider, SPC, discussed this question at a workshop in early 2021 in the context of a retrospective review of the quality of Japanese catch statistics (Working Paper ISC/21/BILLWG-01/05). The differences in catch estimates between the ISC stock assessment and the WCPFC occurs for longline fisheries that record the catch in numbers. These differences in catch estimates are due to the different methods used to convert numbers to biomass for the WCPFC catch estimates and for the stock assessment, whether it is SS or MFCL model. The WCPFC catch estimates conversion is based on the product of the number of fish caught and average weight of the individuals caught on a trip or within the reporting strata. The stock assessment estimates catch as product of the numbers caught, the fishery selectivity function, and the weight-at-age of individuals. When conducting a stock assessment it is important to account for potential conversion error by using the catch in the original recorded units, which for longline fisheries is numbers. The BILLWG noted that in the early part of the longline catch time series prior to 2000, the WCPFC catch estimates did not include Japanese longline training vessel catches. The inclusion of these catches after 2000 resulted in similar trends and catches although small differences remain. Based on these observations, the BILLWG concluded that WCPFC Japanese longline fishery statistics and the output from SS are similar.

2. Explain why the striped marlin stock decreased and the fishing mortality increased after a drastic decrease in fishing effort by high seas driftnet fisheries in the early 1990s.

The BILLWG identified three potential contributing factors: (1) The model assumes that selectivity for Japanese driftnet catches in the 1975-1993 period is the same selectivity as in the Japanese coastal driftnet fishery from 1994 to 2017, although there are no size data available from 1975-1993. The coastal driftnet fishery targets large adult MLS, which means that the model is assuming the majority of the catch from 1975 to 1993 also is large adult fish. In 1994, the majority of the catch is from CCM longline fleets, which caught predominately juvenile MLS. This assumed shift from catching large adults to small juveniles would result in an increase in fishing mortality even if the overall catch decreased; (2) The CPUE time series has a break in 1993 to 1994, which could be driving a shift in the model results due to a lack of continuity; and (3) the Japanese logbook data also change their reporting requirements in 1993 to 1994, which could contribute to the shift in fishing mortality, however not all CCMs agreed that this would drive the change in fishing mortality.

The WG noted that excluding data prior to 1994 in the MLS assessment was explored in the 2019 assessment meeting. The WG compared two models that started in 1994. A sensitivity run fixing the initial equilibrium catch (run 22, MLS SAR, ISC19, Figure 3 a) showed no difference relative to the base-case model results. In contrast, estimating the initial equilibrium catch (Model 2 in the Carvalho, et al. 2019, Figure 3 b) resulted in the same trend but produced different estimates of initial population size. It was noted that SSB<sub>0</sub> is strongly associated with the initial equilibrium catch. However, the WG did not have strong information to justify setting the initial catch (5,000mt). Based on this discussion, the WG agreed to estimate the initial equilibrium catch in the stock assessment model, and agreed that differences due to starting year were likely driven by the uncertainty in catches before 1993.

3. Develop a roadmap to address the issues identified in the latest stock assessment by ISC.

The BILLWG recommends revising its work plan to assess WCNPO MLS in 2022 and postpone the WCNPO SWO assessment to 2023 to address the concerns identified by the questions above and by the WG in its WCNPO MLS stock assessment report (ISC/19/ANNEX/11). For example, there were concerns about providing a rebuilding plan in 2021 and then reassessing the stock in 2022. However, the proposed revised workplan would permit updating of the rebuilding plan after the stock assessment in 2022.

	The WG presented the	following schedule	of uncoming meetings a	s part of its workplan.
--	----------------------	--------------------	------------------------	-------------------------

Year	Meeting	Remarks
October 2021	WCPFC-NC17	Confirm the definition of rebuilding target and suggest the change of stock assessment schedule.
December 2021	WCPFC18	Confirm the definition of rebuilding target and suggest the change of stock assessment schedule.
Mid December 2021	Data preparatory meeting for MLS	
March 2022	Benchmark stock assessment meeting for MLS	
April 2022	Rebuilding meeting for MLS	
November 2022	Data preparatory meeting for SWO	

At its April 2021 BUM stock assessment meeting, the ensemble model for Pacific BUM was finalized, diagnostics were discussed, and projections and sensitivity runs were completed. While the ensemble model approach was not initially planned for Pacific BUM, it became apparent that it was most appropriate approach for this assessment.

#### **Discussion**

The Plenary endorsed the BILLWG's responses to the questions posed by WCPFC17, the request for clarification of the MLS rebuilding target and the BILLWG proposed workplan for 2021-22.

#### 3.3.2 Pacific Blue Marlin Stock Assessment

**Stock Identification and Distribution:** The Pacific blue marlin (*Makaira nigricans*) is considered a pan-Pacific stock caught primarily in tropical and sub-tropical waters. All available fishery data from the IATTC and the WCPFC were used for this benchmark stock assessment. For modeling observations of CPUE and size composition data, it was assumed that there was instantaneous mixing of fish throughout the stock area on a quarterly basis.

Catches: Pacific blue marlin catches increased from the 1970s to the 1990s, and remained high until the 2000s when they started to decline. The relative catch by Japanese fleets has decreased

and the relative catch from the Chinese Taipei and other longline fleets has increased since 2000 (Figure 1). Overall, longline gear has accounted for the majority of Pacific BUM catches (67%), Japanese fleets dominating the catch before 2000, and Chinese Taipei and other longline fleets dominating thereafter.

**Data and Assessment:** Catch and size composition data were collected from three ISC countries (Japan, Chinese Taipei, and the USA), the IATTC, and the WCPFC. Standardized catch-per-unit effort data used to measure trends in relative abundance were provided by Japan, the USA, and Chinese Taipei. The BUM stock was assessed using a two-model ensemble of age- and lengthstructured Stock Synthesis models fit to time series of standardized CPUE and size composition data. The two models in the ensemble differed only in the assumption of the growth curve used. One model used the growth curve from the 2016 Pacific blue marlin assessment (hereafter referred to as the "old growth" model). The other model used a growth curve presented to the working group that was a collaboration between ISC members (hereafter the "new growth" model see Figure 2). The BILLWG noted some substantial differences between the two growth models, including the parameterization (von Bertalanffy vs. two-stanza growth) and the asymptotic length (L<sub>inf</sub>) for old fish, which was about 50 cm larger for the old growth model. Previous work has demonstrated that stock assessment models can be highly sensitive to the L<sub>inf</sub> parameter; therefore, the WG explored both models for their ability to describe the input data. Neither model could be discarded based upon model fit and diagnostics; therefore, biological reference points, spawning stock biomass, and fishing mortality were averaged between the two models using the multivariate lognormal approximation method assuming equal weights. The value for stock-recruitment steepness used for the base case model was h = 0.87. The assessment model was fit to relative abundance indices and size composition data in a likelihood-based statistical framework with smoothing penalties for fishery selectivity. Maximum likelihood estimates of model parameters, derived outputs, and their covariances were used as inputs to the model averaging using the multivariate lognormal approach to characterize stock status and to develop stock projections. Several sensitivity analyses were conducted to evaluate the effects of changes in model parameters, including the natural mortality rate, the stock-recruitment steepness, the growth curve parameters, and the female age at 50% maturity, as well as uncertainty in the input data (i.e., CPUE indices used and the weighting of the size composition data) and model structure (i.e., initial fishing mortality).

**Biological Reference Points:** Biological reference points were computed for the combined ensemble model using a multivariate lognormal approximation that accounts for the inherent covariance between  $F/F_{MSY}$  and  $SSB/SSB_{MSY}$  (Table 2). The combined estimate of the spawning biomass to produce MSY (adult female biomass) was  $SSB_{MSY} = 20,677$  mt. The point estimate of  $F_{MSY}$ , the fishing mortality rate to produce MSY (average fishing mortality on ages 1-10) was  $F_{MSY} = 0.23$  and the corresponding equilibrium value of spawning potential ratio at MSY was  $SPR_{MSY} = 17\%$ .

**Projections:** Stock projections were conducted with Stock Synthesis to evaluate the impact of alternative future levels of harvest intensity on female spawning stock biomass, fishing mortality, and yield for Pacific blue marlin. These projections were considered deterministic, because future recruitment was predicted based on the stock-recruitment curve. These projections used all the multi-fleet, multi-season, size- and age-selectivity, and complexity in the assessment model to produce consistent results. The stock projections started in 2020 and continued through 2029

(10 years) under 4 levels of constant fishing mortality: (1) constant fishing mortality equal to the 2003-2005 average ( $F_{2003-2005}$ ); (2) constant fishing mortality equal to  $F_{MSY}$ ; (3) constant fishing mortality equal to the 2016-2018 average defined as current; and (4) constant fishing mortality equal to  $F_{30\%}$  (corresponding to the fishing mortality that produces 30% of the spawning potential ratio). Stock projections for each F scenario were run for both growth models in the ensemble and combined using the multivariate lognormal method. Using the deterministic projection result, the multivariate lognormal approximation was applied to generate 10,000 trajectories of SSB and F to calculate the model-averaged results of the new and old growth models. Results showed the projected female spawning stock biomasses, fishing mortality, and the catch biomasses under each of the combined scenarios (Table 3 and Figure 5).

#### **Discussion**

The WG Chair was asked about the rationale for using an ensemble model approach. The WG did not make an *a priori* decision to employ an ensemble approach. Rather, model diagnostics indicated both the old growth model used in the previous assessment and the new growth model were equally plausible and both provide useful information about different aspects of growth. The Plenary noted that this is the first use of an ensemble modeling approach in an ISC stock assessment.

The ISC Plenary endorsed the North Pacific BUM stock assessment and considers it to be the best available scientific information on the stock.

#### 3.3.3 Pacific Blue Marlin Stock Status and Conservation Information

Based on the stock assessment results, the Plenary adopted the following stock status and conservation advice for Pacific BUM.

#### **Stock Status**

Stock status, biomass trends, and recruitment of Pacific blue marlin (Makaira nigricans) for both models in the ensemble had similar trends, although the estimates of initial conditions are different. All reported results are the model-averaged estimates from the ensemble model unless otherwise noted. Estimates of population biomass declined until the mid-2000s, increased again until 2021, and has been relatively flat until the present. The minimum spawning stock biomass is estimated to be 17,592 mt in 2006 (5% above SSB<sub>MSY</sub>, the spawning stock biomass to produce MSY, 95% C.I. 14,512-20,703 mt, SSB/SS<sub>MSY</sub> 95% C.I. 0.70-1.01, Figure 3). In 2019, SSB = 24,272 mt and the relative SSB/SSB<sub>MSY</sub> = 1.17 (95% C.I. 0.87-1.51). Combined median fishing mortality on the stock (average F on ages 1-10) is currently below  $F_{MSY}$  (Figure 3). It averaged roughly F = 0.13 during 2017-2019, or 40% below  $F_{MSY}$ , and in 2019, F=0.11 with a relative fishing mortality of  $F/F_{MSY} = 0.50$  (95% C.I. 0.37-0.69). Median fishing mortality has been below F<sub>MSY</sub> every year except 2003 to 2006. The predicted value of the spawning potential ratio (SPR, the predicted spawning output at current F as a fraction of unfished spawning output) is currently  $SPR_{2017-2019} = 31\%$  for the combined model, which is above the SPR required to produce MSY (17%). Recruitment was relatively consistent throughout the assessment time period, with occasional pulses in recruitment, but no notable periods of below-average recruitment (Figure 3). No target or limit reference points have been established for Pacific BUM under the auspices of the WCPFC. Blue marlin is expected to be highly productive due to its rapid growth and high resilience to reductions in spawning potential. Although fishing mortality has approached MSY and exceeded MSY from 2003 to 2006, the biomass of the stock has remained above MSY (Figure 4). With continued decreases in Pacific BUM catch and fishing effort, the stock is expected to remain within MSY limits. When the status of BUM is evaluated relative to MSY-based reference points, the 2019 spawning stock biomass of 24,272 mt is 17% above  $SSB_{MSY}$  (20,677 mt, 95% C.I. -13% to +50%) and the 2017-2019 fishing mortality is 50% below  $F_{MSY}$  (95% C.I. 37% to 69%) (Table 2).

Based on these findings, the following information on the status of the WCNPO Blue Marlin stock is provided:

- 1. No target or limit reference points have been established for Pacific blue marlin by the WCPFC;
- 2. Female spawning stock biomass was estimated to be 24,241 mt in 2019, or about 17% above SSB<sub>MSY</sub> and 17% above 20%SSB<sub>0</sub>.
- 3. Fishing mortality on the stock (average F, ages 1 to 10) averaged roughly F = 0.13 during 2016-2019, or about 40% below  $F_{MSY}$  and 28% below  $F_{20\%SSB0}$ .
- 4. Blue marlin stock status from the ensemble model indicates that relative to MSY-based reference points, overfishing was very likely not occurring (>90% probability) and Pacific blue marlin is likely not overfished (81% probability, Figure 4).

#### **Conservation Information**

The Pacific blue marlin stock has produced annual yields of around 18,800 mt per year since 2015, or about 90% of the MSY catch. Blue marlin stock status from the ensemble model indicates that the current median spawning biomass is above SSB<sub>MSY</sub> and that the current median fishing mortality is below F<sub>MSY</sub>. However, uncertainty in the stock status indicates a 19% chance of Pacific blue marlin being overfished relative to SSB<sub>MSY</sub>. Both the old and new growth models show evidence of spawning biomass being above SSB<sub>MSY</sub> and fishing mortality being below F<sub>MSY</sub> during the last 5 years. Catch biomass has been declining for the last 5 years, and therefore the stock has a low risk of experiencing overfishing or being overfished unless fishing mortality increases to above F<sub>MSY</sub> based upon stock projections (Table 3, Figure 5). However, it is also important to note that retrospective analyses show that the assessment model tends to overestimate biomass and underestimate fishing mortality in recent years, in part due to rapid changes in longline CPUE.

Based on these findings, the following conservation information is provided:

- 1. There is no evidence of excess fishing mortality above FMSY (F2016-2019 is 40% of FMSY) or substantial depletion of spawning potential (SSB2019 is 17% above SSBMSY);
- 2. It is important to note that retrospective analyses show that the assessment model appears to overestimate spawning stock biomass in recent years; and
- 3. The results show that projected female spawning biomass is expected to increase under the  $F_{\text{status quo}}$  and  $F_{30\%}$  harvest scenarios and decline to SSB<sub>MSY</sub> under the High F and  $F_{MSY}$  harvest scenarios. The probability that the stock is overfished or overfishing occurring by 2029 under each harvest scenario is low.

#### **Special Comments**

- 1. Uncertainty regarding the choice of BUM growth curve led to the ensemble model approach for this assessment. The BILLWG recognized that there is considerable uncertainty in input CPUE data in the recent years and life history parameters, especially growth. The BILLWG considered an extensive suite of model formulations and associated diagnostics for developing the assessment models. Overall, the BILLWG found issues with both the new growth and old growth model diagnostics and sensitivity runs that are consistent with the presence of data conflicts, but none of the model diagnostics show that the results of either model were invalid. It is recommended model development work to reduce data conflicts and modeling uncertainties continue and that input assessment data be reevaluated to improve the time series.
- 2. It is recommended that biological sampling to improve life history parameter estimates continue to be collected and ISC countries participate in the BILLWG International Biological Sampling program to improve those estimates.

Table 1. Reported catch (tonnes, mt) used in the stock assessment along with annual model-averaged estimates of female spawning biomass (tonnes, mt), relative female spawning biomass ( $SSB/SSB_{MSY}$ ), recruitment (thousands of age-0 fish), fishing mortality (average F, ages 1-10), relative fishing mortality ( $F/F_{MSY}$ ), and spawning potential ratio (SPR) of Pacific blue marlin..

Year	2013	2014	2015	2016	2017	2018	2019	Mean <sup>1</sup>	Min <sup>1</sup>	Max <sup>1</sup>

Figure 1. Annual catch biomass (tonnes, mt) of Pacific blue marlin (*Makaira nigricans*) by country for Japan, Chinese Taipei, the U.S.A., and all other countries during 1975-2019.

Figure 2. Length-at-age for Pacific blue marlin from the old growth model (von-Bertalanffy curve, black lines) and the new growth model (Richards curve, blue lines) by sex (females diamonds, males circles) used in the 2021 assessment..

Figure 3. Time series of estimates of female spawning stock biomass over female spawning stock biomass at MSY (top left), fishing mortality over fishing mortality at MSY (top right), spawning stock biomass (center left), instantaneous fishing mortality (ages 1-10 year<sup>-1</sup>, center right), recruitment (age-0 fish, bottom left), and catch (bottom right) for Pacific blue marlin (*Makaira nigricans*) derived from the 2021 stock assessment model ensemble. Lines (or points for recruitment) indicate the median value estimated from the joint multivariate delta-lognormal estimation, shaded areas (or error bars for recruitment) indicate the 95% confidence intervals. Unweighted indicates that both models have equal weights in the ensemble.

Figure 4. Kobe plot of the time series of estimates of relative fishing mortality (average of age 1-10) and relative spawning stock biomass of Pacific blue marlin (*Makaira nigricans*) during 1971-2019. The white circle denotes the delta-lognormal multivariate estimate of the ensemble model in 2019, blue dots indicate the final year stock status of the old growth model with the 10,000 multivariate draws, and red dots indicate the final year stock status of the new growth model with the 10,000 multivariate draws.

Figure 5. Historical and projected trajectories of spawning biomass and total catch from the Pacific blue marlin ensemble models based upon the four F scenarios: projected spawning biomass, dotted line indicates SSB<sub>MSY</sub>, shading indicates 95% confidence intervals (top); projected instantaneous fishing mortality (ages 1-10 year<sup>-1</sup>), dotted line indicates  $F_{MSY}$ , shading indicates 95% confidence intervals (center); and projected catch (tonnes, mt; bottom). Green indicates scenario 1,  $F_{2003-2005}$ ; red indicates scenario 2,  $F_{MSY}$ ; yellow indicates scenario 3,  $F_{2016-2018}$ ; and blue indicates scenario 4,  $F_{30\%}$ . The list of projection scenarios can be found in Table 3.

## 3.3.4 Western and Central North Pacific Swordfish Stock Status and Conservation Information

H. Ijima, the BILLWG Chair, noted that the WCNPO SWO stock was last assessed in 2018 and that the next assessment is planned for 2023.

The Plenary reviewed and agreed to forward the stock status and conservation information adopted at ISC20 (see Section 3.3.3, pp. 37-39 in the <u>ISC20 Plenary Report</u>) unchanged, except for the omission of accompanying figures and tables and slight clarifying modifications.

#### **Stock Status**

Estimates of total stock biomass show a relatively stable population, with a slight decline until the mid-1990s followed by a slight increase since 2000. Population biomass (age-1 and older) averaged roughly 97,919 t in 1974-1978, the first 5 years of the assessment time frame, and has declined by only 20% to 71,979 t in 2016. Female SSB was estimated to be 29,403 t in 2016, or about 90% above SSB<sub>MSY</sub>. Fishing mortality on the stock (average F, ages 1 – 10) averaged roughly F = 0.08 yr<sup>-1</sup> during 2013-2015, or about 45% below F<sub>MSY</sub>. The estimated SPR (the predicted spawning output at the current F as a fraction of unfished spawning output) is currently SPR<sub>2016</sub>= 45%. Annual recruitment averaged about 717,000 fish during 2012-2016, and no long-term trend in recruitment was apparent. Overall, the time series of spawning stock biomass and recruitment estimates show a stable spawning stock biomass and a fluctuating pattern without trend for recruitment. The Kobe plot depicts the stock status relative to MSY-based reference points for the base case model and shows that spawning stock biomass declined to almost the MSY level in the mid-1990s, but SSB has remained above SSB<sub>MSY</sub> throughout the time series.

Biomass status is based on female SSB in the 2018 benchmark assessment, whereas in the 2014 update assessment biomass status was based on exploitable biomass (effectively age-2+ biomass). It is also important to note that there are no currently agreed upon reference points for the WCNPO SWO stock and that retrospective analyses show that the assessment model appears to underestimate spawning stock biomass in recent years.

Based on these findings, the following information on the status of the WCNPO SWO stock is provided:

- 1. The WCNPO SWO stock has produced annual yields of around 10,200 t per year since 2012, or about two-thirds of the MSY catch amount;
- 2. There is no evidence of excess fishing mortality above FMSY (F2013-2015 is 45% of FMSY) or substantial depletion of spawning potential (SSB2016 is 87% above SSBMSY);
- 3. Overall, the WCNPO SWO stock is not likely overfished and is not likely experiencing overfishing relative to MSY-based or 20% of unfished spawning biomass-based reference points.

#### **Conservation Information**

Stock projections were conducted using a two-gender projection model. The five stock projection scenarios were: (1) F status quo, (2) F<sub>MSY</sub>, (3) F at 0.2\*SSB<sub>F=0</sub>, (4) F<sub>20%</sub>, and (5) F<sub>50%</sub>. These projection scenarios were applied to the base case model results to evaluate the impact of alternative levels of fishing intensity on future spawning biomass and yield for SWO in the WCNPO. The projected recruitment pattern was generated by stochastically sampling the estimated stock-recruitment model from the base case model. The projection calculations employed model estimates for the multi-fleet, multi- season, size- and age-selectivity, and structural complexity in the assessment model to produce consistent results.

Based on these findings, the following conservation information is provided:

- 1. The results show that projected female spawning biomass is expected to increase under all of the harvest scenarios, with greater increases expected under lower fishing mortality rates; and
- 2. Similarly, projected catch is expected to increase under each of the five harvest scenarios, with greater increases expected under higher fishing mortality rates.

## 3.3.5 Eastern Pacific Swordfish Stock Status and Conservation Information

H. Ijima, the BILLWG Chair, noted that the EPO SWO stock was last assessed in 2018 and that the IATTC is planning an assessment based on new boundaries in 2022.

#### **Discussion**

The Plenary discussed the proposed change in stock boundaries for swordfish at length. It was noted that IATTC is planning to conduct an assessment for the EPO stock south of 10°N latitude and east of 150°W longitude. The BILLWG has proposed conducting a WCNPO SWO assessment including the EPO area southeast of the current stock boundary to the Americas as a separate area. The BILLWG Chair explained that the proposed change to the stock boundaries is based on new movement information from tagging studies (Sepulveda et al. 2020<sup>4</sup>; BILLWG discussion summarized in ISC/21/ANNEX/08). It was also noted that there may be some stock mixing between WCNPO and EPO SWO in the roughly triangular area defined by the current stock boundary, 10°N latitude, and the coast of the Americas.

It was also noted that SPC-OFP is planning an assessment of the SWO stock in the South Pacific west of 150°W longitude for the WCPFC. The BILLWG noted that a more detailed analysis would need to be undertaken to incorporate fully the newest data on swordfish stock boundaries in order to produce a scientifically supported new stock boundary. The Plenary recommended that the BILLWG, IATTC scientific staff, and SPC-OFP staff closely coordinate on defining stock boundaries in preparation for assessments to ensure a consistent approach and scientifically defensible boundaries.

The Plenary noted that the current stock status and conservation advice for EPO SWO, carried forward from ISC20 is based on the pre-existing stock boundary and is inconsistent with stock boundaries proposed for future assessments in the north and south EPO.

#### **Stock Status and Conservation Information**

The Plenary reviewed and agreed to forward the stock status and conservation information adopted at ISC20 (see Section 3.3.4, pp. 39-40 in the <u>ISC20 Plenary Report</u>) unchanged, except for the omission of accompanying figures and tables.

<sup>&</sup>lt;sup>4</sup> Sepulveda, C.A., Wang, .M, Aalbers, S.A., and Alvarado-Bremer, J.R., 2020. Insights into the horizontal movements, migration patterns, and stock affiliation of California swordfish. Fisheries Oceanography 29:152-168.

#### **Stock Status**

Exploitable biomass (age 2+) of the EPO SWO stock decreased during the 1969-1995 period and increased from 31,000 t in 1995 to over 60,000 t by 2010, generally remaining above  $B_{MSY}$ . Harvest rates were initially low, have had a long-term increasing trend, and likely exceeded  $H_{MSY}$  in 1998, 2002, 2003, as well as in 2012, the terminal year of the last stock assessment.

Based on these findings, the following information on the status of the EPO SWO stock is provided:

- 1. No target or limit reference points have been established for the EPO SWO stock under the auspices of the IATTC. Stock status is assessed relative to MSY-based reference points;
- 2. The Kobe plot shows that overfishing likely occurred (>50%) relative to potential MSY-based reference points in the late 1990s and early 2000s and from 2010 to 2012;
- 3. There was a 55% probability that overfishing occurred in 2012, but there was less than a 1% probability that the stock was overfished relative to MSY-based reference points.

#### **Conservation Information**

Stochastic projections for the EPO SWO stock show that exploitable biomass will likely have a decreasing trajectory during 2014-2016 under the eight harvest scenarios examined. Under the high harvest rate scenarios (status quo catch, maximum observed harvest rate, 150% of  $H_{MSY}$ ), exploitable biomass was projected to decline to 31,170 t ( $B_{MSY}$ ) by 2016 with corresponding harvest rates above  $H_{MSY}$ . In comparison, under the status quo harvest rate scenario, exploitable biomass was projected to decline to 40,000 t by 2016, well above the  $B_{MSY}$  level. Overall, the projections showed that if recent high catch levels (9,700 t) persist, then exploitable biomass will decrease and a moderate risk (50%) of overfishing will continue to occur.

The risk analyses for harvesting a constant catch of EPO SWO during 2014-2016 showed that the probabilities of overfishing and becoming overfished increased as projected catch increased in the future. Maintaining the current (2010-2012) catch of EPO SWO of approximately 9,700 t would lead to a 50% probability of overfishing in 2016 and a less than 1% probability of the stock being overfished in 2016.

Based on these findings, the following conservation information is provided:

- 1. For the EPO SWO stock, overfishing may have occurred (<50%) from 2010 to 2012, and the average yield of roughly 10,000 t in those years, or almost two times higher than the estimated MSY, is not likely to be sustainable in the long term;
- 2. While biomass of the EPO stock appears to be nearly twice  $B_{\rm MSY}$ , any increases in catch above recent (3-year average 2010-2012) levels should consider the uncertainty in stock structure and unreported catch.

# 3.3.6 Pacific Striped Marlin Stock Status and Conservation Information

H. Ijima, Chair of the BILLWG, noted that WCNPO MLS was last assessed in 2019.

### **Stock Status and Conservation Information**

The Plenary reviewed and agreed to forward the same stock status information that was adopted by ISC20 (see Section 3.3.2, pp. 33-37 in the <u>ISC20 Plenary Report</u>) unchanged, except for the omission of accompanying figures and tables and slight clarifying modifications. Furthermore, the Plenary agreed to an addition to the conservation information adopted by ISC20 in light of questions and clarifications regarding the rebuilding plan (see Section 3.3.1 of this report) initiated by the WCPFC. The ISC Plenary also reiterates the concerns expressed by the BILLWG in their special comments about the stock assessment (ISC/19/ANNEX/11) that are reproduced below.

### **Stock Status**

Biomass (age 1 and older) for the WCNPO MLS stock decreased from 17,000 t in 1975 to 6,000 t in 2017. Estimated fishing mortality averaged F=0.97 yr<sup>-1</sup> during the 1975-1994 period with a range of 0.60 to 1.59 yr<sup>-1</sup>, peaked at F=1.71 yr<sup>-1</sup> in 2001, and declined sharply to F=0.64 yr<sup>-1</sup> in the most recent years (2015-2017). Fishing mortality has fluctuated around  $F_{MSY}$  since 2013. Compared to MSY-based reference points, the current spawning biomass (average for 2015-2017) was 76% below SSB<sub>MSY</sub> and the current fishing mortality (average for ages 3 – 12 in 2015-2017) was 7% above  $F_{MSY}$ .

Based on these findings, the following information on the status of the WCNPO MLS stock is provided:

- 1. There are no established reference points for WCNPO MLS;
- 2. Results from the base case assessment model show that under current conditions the WCNPO MLS stock is overfished and is subject to overfishing relative to MSY-based reference points.

#### **Conservation Information**

The status of the WCNPO MLS stock shows evidence of substantial depletion of spawning potential (SSB<sub>2017</sub> is 62% below SSB<sub>MSY</sub>), however fishing mortality has fluctuated around F<sub>MSY</sub> in the last four years. The WCNPO MLS stock has produced average annual yields of around 2,100 t per year since 2012, or about 40% of the MSY catch amount. However, the majority of the catch are likely immature fish. All the projections show an increasing trend in spawning stock biomass during the 2018-2020 period, with the exception of the high F scenario under the short-term recruitment scenario. This increasing trend in SSB is due to the 2017 year class, which is estimated from the stock-recruitment curve and is more than twice as large as recent average recruitment.

Based on these findings and the ISC conclusion on recruitment scenarios, the following conservation information is provided:

- 1. In response to a request from NC15, both long-term and short-term recruitment scenarios were evaluated. The ISC concluded that the short-term recruitment model was the most appropriate model to use for conducting stochastic stock projections for WCNPO MLS because the time trend in the recruitment is not captured by the long term recruitment scenario;
- 2. If the stock continues to experience recruitment consistent with the short term recruitment scenario (2012-2016), then catches must be reduced to 60% of the WCPFC catch quota from CMM 2010-01 (3,397 t) to 1,359 t in order to achieve a 60% probability of rebuilding to 20%SSB<sub>0</sub>=3,610 t by 2022. This change in catch corresponds to a reduction of roughly 37% from the recent average yield of 2,151 t.
- 3. The Interim Rebuilding Plan for North Pacific Striped Marlin (Attachment L, WCPFC16 Summary Report) was adopted by WCPFC16 in 2019. The ISC responded to several technical questions during ISC21 and based on these responses (see Section 3.3.1 and ISC/21/ANNEX/08) recommends that the next WCNPO MLS stock assessment be completed in 2022 followed by updating of the rebuilding plan using the latest scientific information. Further, the ISC seeks clarification prior to the assessment on whether or not the rebuilding target, 20%SSB<sub>F=0</sub>, is based on dynamic biomass. If the rebuilding target is based on dynamic biomass, then a target rebuilding date will be needed for the projections to support the rebuilding plan.

It was also noted that retrospective analyses (ISC/19/ANNEX/11) show that the assessment model appears to overestimate spawning potential in recent years, which may mean the projection results are ecologically optimistic.

### **Special Comments**

The WG achieved a base-case model using the best available data and biological information. However, the WG recognized uncertainty in some assessment inputs including drift gillnet catches and initial catch amounts, life history parameters such as maturation and growth, and stock structure.

Overall, the base case model diagnostics and sensitivity runs show that there are some conflicts in the data (ISC/19/ANNEX/11). When developing a conservation and management measure to rebuild the resource, it is recommended that these issues be recognized and carefully considered, because they affect the perceived stock status and the probabilities and time frame for rebuilding of the WCNPO MLS stock.

#### Research Needs

To improve the stock assessment, the WG recommends continuing model development work, to reduce data conflicts and modeling uncertainties, and reevaluating and improving input assessment data.

### 3.4 Sharks

### 3.4.1 SHARKWG Report and Review of Assignments

M. Kai, SHARKWG Chair, provided a summary of SHARKWG activities over the past year (ISC/21/ANNEX/04). The focus of the SHARKWG was mainly on SMA with the goal of completing an indicator-based analysis by the ISC21 Plenary. This indicator-based analysis was requested in response to the ISC20 Plenary approving a change in the schedule for benchmark stock assessments of BSH and SMA from 3 to 5 years. The SHARKWG met virtually 22-26 February 2021, to conduct the SMA indicator-based analysis in addition to the discussing administrative matters and planning future SHARKWG activities. The SHARKWG also held an online meeting before the full meeting (17 September 2020) to (1) discuss which indicators should be used for SMA and (2) to discuss how an indicator approach should be presented. The WG decided to use annual catch and standardized CPUE up to 2019 as key indicators, supplemented by size-frequency data. The purpose of the analysis was to detect major changes in abundance and fishing pressure as triggers for a new assessment rather than updating stock status and conservation information based on the results.

The WG Chair briefly presented highlights of the WG meetings to the Plenary; **ISC/21/ANNEX/04** contains the report of the 22-26 February 2021 SHARKWG meeting and the 17 September 2020 intersessional meeting. The WG Chair expressed appreciation to all participants in the SHARKWG meeting for their hard work at the meetings and during the intersessional webinar, on the SMA indicator-based analysis (**ISC/21/ANNEX/05**).

In conclusion, there were no obvious signs of major shifts in the tracked indicators that would necessitate a revision to the current stock assessment schedule for SMA. The SHARKWG therefore plans to conduct the next benchmark stock assessment for SMA in 2024, as scheduled.

T1 111/C 1	41 C	11 ' ' ' '	' ' 1	1	1 4 1	. 1 . 6	າ 1

Potential Timing	Location	Purpose
OctDec. 2021	Japan or Chinese Taipei (depending on COVID-19 situation)	BSH data preparatory for stock assessment
Dec. 2021-Feb 2022	online	BSH pre-stock assessment meeting
Mar,-May 2022	TBD	BSH stock assessment meeting

### **Discussion**

The SHARKWG described two issues in the previous BSH stock assessment that will be addressed in the upcoming assessment scheduled for 2022. First, species-specific catch data are unavailable for most of the Japanese fleet prior to 1994 and catch data from the Japan high seas driftnet fishery are particularly uncertain. Second, the stock-recruit relationship was poorly specified in the previous assessment. The low fecundity of BSH has made it difficult to specify

the appropriate relationship. The WG will update the growth curve, age-at-maturity, and the age-specific mortality schedule to improve the estimate of the stock-recruit relationship.

The Plenary approved the SHARKWG workplan for 2021-22.

### 3.4.2 Shortfin Mako Shark Indicator Analysis

M. Kai, SHARKWG Chair, presented the results of the indicator-based analysis of SMA in the NPO conducted in 2021 (ISC/21/ANNEX/05). A benchmark stock assessment was completed in 2018 with the next full benchmark scheduled for 2024. In the interim, an indicator-based analysis was conducted to monitor key indicators for signs of potential changes in the stock abundance or fisheries dynamics that could warrant a shift in the schedule for the next benchmark assessment. For the present analysis, annual trends in all available catch data (F1-F19) from 1957 to 2019 and seven abundance indices (S1-S7) from 1992-2019 were visually inspected. Length frequency data were also used alongside the catch and the abundance indices as supplemental information for the indicator-based analysis.

Catch was estimated for multiple fleets and nations based on the best available information. Catch estimates for each fishery were made based on fishing effort, knowledge of the species composition of the catch, estimated CPUE, and scientific knowledge of the operations and catch history. Species-specific SMA catch was available for all major fisheries since 1993; however, catch for the early period, from 1957 up to 1993, is highly uncertain. The highest catches came from Taiwan (F7-9), Japan (F10-14), and Mexico (F15-16) (Figure 6). After 2016, the last year of data in the 2018 benchmark stock assessment, the catch amount in 2019 reached its second highest value during the last decade. Recent increases in annual catches from 2017 to 2019 may be a sign of an increase in population size; however, this increase also could be explained by an increase in fishing pressure. The uncertainty surrounding this uptick in recent catch makes current catch data alone insufficient for describing the stock status of SMA in the NPO.

The four major abundance indices (S1: US Hawaii longline shallow-set; S3: Taiwan longline large-scale; S5: Japan research and training vessels; and S7: Mexico observer for longline) used in the base case benchmark stock assessment in 2018 were also used in this analysis as key indicators to determine whether the next benchmark stock assessment, scheduled for 2024, should be expedited. The scaled CPUEs showed a stable and slightly increasing trend in the four major fleets (Figure 7). A five-year moving average of CPUE, an approach used to reduce the effect of large fluctuations in CPUEs from year to year, was also used to examine trends in the abundance indices. The moving average of CPUE (Figure 8) reflected the trends of annual CPUEs with more smoothing (Figure 7). The moving average of CPUE for three surveys (S1, S3, and S5) showed an increasing trend throughout the period for which data were available. In contrast, the moving average of the S7 CPUE index showed a slight decrease up until 2018, followed by a large increase in 2019.

Percent changes in the moving average of annual CPUE over the long-term (the whole period for which CPUE data was available) and over the short term (the most recent 5 years) were used to evaluate historical and recent changes in the indices of relative abundance for the four major fleets. The percent change in the moving average of CPUE in the long-term series for four major fleets indicated positive values while the percent change in the short-term series indicated

slightly negative values for S3 and S7 (Table 4). These results showed that the indices of relative abundance of SMA in the NPO exhibited no signals of population decline since the 1990s.

In conclusion, based on updated data for the abundance indices and length frequencies used in the base case benchmark assessment of SMA in 2018, no signs of shifts in stock abundance or fishery dynamics were apparent. As such, the SHARKWG concluded that there was no reason to shift the schedule for the next benchmark stock assessment of SMA, currently scheduled for 2024.

As a research need, threshold values of key indicators (i.e., indices of relative abundance) should be explored to help in determining when shifts may be needed in the benchmark stock assessments schedule.

### **Discussion**

The Plenary discussed the conditions under which indicator analyses like the just completed SMA analysis, should be carried out. This discussion of included workload considerations relative to the usefulness of the information derived for determining a need to expedite a benchmark assessment for a stock. The history of the use of indicator analyses by the ISC was reviewed. Generally, the rationale for conducting these analyses relates to the shift from a three-year to a five-year assessment cycle for selected stocks. The shift in the assessment cycle for these stocks is premised on information indicating the stocks are healthy and trends in status are stable.

The Plenary agreed that a specified set of rules and procedures should be adopted to decide the timing and frequency of these indicator analyses. One option discussed is to develop a set of criteria to determine whether the results of the most recent benchmark stock assessment indicate the need to conduct an interim indicator analysis. Another option is to simply default to conducting an indicator analysis at the midpoint of a five-year assessment cycle. This latter option would be premised on a methodology that does not demand substantial work that would impinge on other workload priorities.

The Plenary tasked the WG to develop recommendations on a decision framework and process for conducting indicator analyses.

Table 4. Percent change of moving average of CPUE for four major fleets (S1, S3, S5 and S7) used in the benchmark stock assessment in 2018. Moving averages were calculated using the mean value of CPUE for five years. The percentage indicates the positive and negative change in the moving average of CPUE between the start and end years from long term (all years with data) and short term (the most recent 5 years). The last year of S5 was removed from the calculation due to data from 2020 being preliminary. S1\_US\_SS (US Hawaii longline shallow-set), S3\_TW\_LALL (Taiwan longline large-scale), S5\_JP\_RTV (Japan research and training vessels), and S7 MX OBS (Mexico observer for longline)...

Period	S1	<b>S3</b>	S5	<b>S</b> 7
Long term (all years with data)	16%	39%	93%	10%
Short term (the most recent 5 years)	23%	-13%	47%	-5%

Figure 6. Annual catch (tonnes, MT) of shortfin make in the North Pacific Ocean by fishery (fleet) from 1954 to 2019. Catch of some fleets are removed from this figure due to different units of catch.

Figure 7. Annual indices of relative abundance of shortfin make in the North Pacific Ocean from 1992 to 2019 (CPUE of each year relative to average CPUE) for four major fleets (S1, S3, S5 and S7) used in the previous benchmark stock assessment in 2018. S1\_US\_SS (US Hawaii longline shallow-set), S3\_TW\_LALL (Taiwan longline large-scale), S5\_JP\_RTV (Japan research and training vessels), and S7\_MX\_OBS (Mexico observer for longline).

Figure 8. Annual 5-year moving average of CPUE for major fleets (S1, S3, S5 and S7) used in the previous benchmark stock assessment in 2018. S1\_US\_SS (US Hawaii longline shallow-set), S3\_TW\_LALL (Taiwan longline large-scale), S5\_JP\_RTV (Japan research and training vessels), and S7\_MX\_OBS (Mexico observer for longline).

### 3.4.3 Blue Shark Stock Status and Conservation Information

M. Kai, SHARKWG Chair, noted that an update stock assessment was completed in 2019 and that the next benchmark stock assessment is scheduled for completion in 2022.

### **Stock Status and Conservation Information**

The Plenary reviewed and agreed to forward the stock status and conservation information adopted at ISC20 (see Section 3.4.2, pp. 42-47 in the <u>ISC20 Plenary Report</u>) unchanged, except for the omission of accompanying figures and tables.

Target and limit reference points have not yet been established for pelagic sharks in the Pacific Ocean by either the WCPFC or the IATTC. Stock status is reported in relation to MSY-based reference points. The following information on the status of NP BSH is provided.

### **Stock Status**

1. Female spawning biomass in 2015 (SSB2015) was 69% higher than at MSY and estimated to be 295,774 t;

- 2. The recent annual fishing mortality (F2012-2014) was estimated to be well below FMSY at approximately 38% of FMSY;
- 3. The reference run produced terminal conditions that were predominately in the lower right quadrant of the Kobe plot (not overfished and overfishing not occurring).

#### **Conservation Information**

Future projections under different fishing mortality (F) harvest policies (status quo, +20%, -20%, F<sub>MSY</sub>) show that median BSH spawning biomass in the NPO will likely remain above SSB<sub>MSY</sub> in the foreseeable future. Other potential reference points were not considered in these evaluations.

The Plenary noted that the average annual catch of BSH by ISC members in 2012-2014 was 29,992 t and that the average annual catch in the 2015-2019 period was 25,742 t. As ISC member countries account for at least 90% of the overall catch, these figures are believed to provide a reliable estimator of catch in North Pacific BSH.

### 3.4.4 Shortfin Mako Shark Stock Status and Conservation Information

M. Kai, SHARKWG Chair, noted that SMA was last assessed in 2018 and an indicator analysis was completed in 2021.

### **Stock Status and Conservation Information**

Based on the conclusions of the SMA indicatory analysis, the Plenary agreed to forward the stock status and conservation information adopted at ISC20 (see Section 3.4.3, pp. 47-48 in the ISC20 Plenary Report) unchanged, except for the omission of accompanying figures and tables.

#### **Stock Status**

The reproductive capacity of the North Pacific SMA stock was calculated as spawning abundance (SA; i.e., number of mature female sharks) rather than spawning biomass, because the number of pups produced is not related to female size (i.e., larger female sharks do not produce more pups). Spawning potential ratio (SPR) was used to describe the impact of fishing on this stock. The SPR of this population is the ratio of SA per recruit under fishing to the SA per recruit under virgin (or unfished) conditions. Therefore, 1-SPR is the reduction in the SA per recruit due to fishing and can be used to describe the overall impact of fishing on a fish stock.

- 1. Target and limit reference points have not been established for pelagic sharks in the Pacific Ocean. Stock status is reported in relation to MSY-based reference points.
- 2. The results from the base case model and six sensitivity analyses that represent the most important sources of uncertainty in the assessment show that the NPO shortfin make stock is likely (>50%) not in an overfished condition and overfishing is likely (>50%) not occurring relative to MSY-based abundance and fishing intensity reference points.

#### **Conservation Information**

Stock projections of biomass and catch of NPO SMA from 2017 to 2026 were performed assuming three alternative constant fishing mortality scenarios: 1) status quo, average of 2013-2015 ( $F_{2013-2015}$ ); 2)  $F_{2013-2015} + 20\%$ ; and 3)  $F_{2013-2015} - 20\%$ .

Based on these future projections, the following conservation information is provided:

- 1. In scenarios where fishing mortality remains constant at F<sub>2013-15</sub> or is decreased by 20%, then spawner abundance (SA the number of mature female sharks) is expected to increase gradually;
- 2. If fishing mortality is increased by 20% relative to F2013-2015, then SA is expected to decrease in the final years of the projection;
- 3. It should be noted that, given the uncertainty in fishery data and key biological processes within the model, especially the stock recruitment relationship, the models' ability to project into the future is highly uncertain.

The ISC Plenary notes that the average annual catch of SMA by ISC members was 1,392 t in the 2013-2015 period and decreased to 1,180 t from 2016-2019.

### 3.5 Observer Comments

Several observers participated in the ISC21 Plenary Sessions and were provided with an opportunity to address the Plenary during each session. Their comments and observations over four sessions are summarized below in the same order as the agenda. These comments have been edited so that they conform to the style of this report, but their content has not been changed.

Pew welcomed the completion of the MSE of NPALB as robust and offering a wide array of harvest strategies for consideration and adoption. Pew asked whether the video presentations being prepared for the WCPFC-SC and WCPFC-NC would be made publicly available to help stakeholders learn more about the MSE.

Pew urged the ISC to move forward with a MSE of PBF. If the ISC is uncertain how to proceed or lacks information to proceed, then Pew urged the ISC to send a clear request for guidance to the IATTC-NC Joint Working Group on PBF Management this year. Pew pointed out that the WCPFC-NC and IATTC have requested that the ISC complete the MSE by 2024 – a request reiterated in 2020 by the WCPFC-NC Chair. The WCPFC harvest strategy for PBF includes a list of management objectives. In 2019, a list of candidate reference points and harvest control rules for testing in the MSE was agreed by the joint working group, as well as a terms of reference to clarify the roles and responsibilities of the ISC and joint working group. Pew expressed concern that relying on the stock assessment and projections for future management is not sufficient as PBF requires a modernized, long-term approach to management. Pew reiterated that the need for the MSE is clear.

WWF Japan welcomed the ISC's decision to discuss at a Sixth Meeting of the IATTC-WCPFC NC Joint Working Group on the lack of input from managers on management objectives and alternative management procedures for PBF, which has contributed to a lack of progress on the

MSE process for this stock. In addition, WWF Japan stressed the importance of continue to improve the accuracy of data collection through actions such as increased observer coverage and electronic monitoring.

Wild Oceans expressed concern about the proposal to move the boundary of the WCNPO SWO stock, asked whether and how recent genetic research was considered, and suggested the ISC work to align the boundaries with the other scientific bodies before the next round of SWO stock assessments.

Wild Oceans sees the expedited MLS assessment as an opportunity for the BILLWG to consider important questions about the stock and rebuilding goals. More specifically, Wild Oceans asked the ISC to consider adjusting the stock assessment and rebuilding plan to account for uncertainty in MLS catch and discards. Recent catch may be significantly above what is reported and scientists should consider including the highest possible value of mortality that includes unreported catch and discards. Additionally, Wild Oceans highlighted the need for further research analyzing how well measures such as release of live marlin, use of circle hooks and other gear modifications can reduce catch and mortality and help achieve the rebuilding goal.

### 4 REVIEW OF STATISTICS AND DATABASE ISSUES

### 4.1 STATWG Report

F. Carvalho, the Chair of the STATWG, summarized the STATWG activities since ISC20 (ISC/21/ANNEX/14). The STATWG meeting was held virtually on July 6 and 7, 2021 with participants from Canada, Chinese Taipei, Japan, Korea, USA, and the WCPFC. Regarding the status of the STATWG, six of the ten items in the 2020-2021 work plan were completed. The "Data share space" designed for the WGs to share files during their work processes has been activated. The ISC website was updated with scheduled Working Group meetings, working papers, stock assessments, fishery statistics, and the ISC organization chart. The uncompleted workplan items include:

- 1. Development of error-checking protocols to be used to post-data submission by Data Correspondents to confirm the quality of the data in the database;
- 2. The STATWG will pursue harmonizing the ISC data submission formats with those used by the WCPFC and the IATTC;
- 3. The STATWG Steering Group will hold an intersessional meeting or conference call/webinar January 2022 to conduct work to complete this work plan; and
- 4. The STATWG Chair, Vice-Chair and other interested parties will continue to develop a Non-Disclosure Agreement (NDA) for data sharing requests. This NDA will incorporate comments from ISC20 and will be reviewed at the next STATWG meeting. A standard operating protocol will be developed to handle data sharing.

It was noted that all ISC Members except China have submitted their Category I and II data and metadata. Discrepancies noted from cross-comparisons between the data submitted by Members and the data in their national reports will be distributed to Members for confirmation and correction. Japan revised the catch in weight data "Category 1c" of SMA for 1994-2019 in ISC21/STATWG/WP/01. These annual catches estimates are based on annual CPUEs and the

proportion of the catches and in this case the proportion of catches attributed to SMA changed. It was noted that species WGs are requested to submit stock assessment data files by November 1 each year for archiving purposes and that this was completed for assessments conducted through 2021. It also was noted that the goal of the stock assessment archive was to increase transparency and to publish the assessment files on ISC researcher's website, which has access restricted to species WG members.

The STAWG Chair discussed the draft NDA for confidential ISC stock assessment data and modeling files. The Chair noted that the draft NDA was a template for a contract between the two parties that outlines confidential data that the parties wish to share for a specified scientific purpose but that the ISC is restricting access. The Chair emphasized that the template would need to be modified for specific applications.

The STATWG discussed the function of the working group. The STATWG members agreed that the STATWG was needed on an ongoing basis in order to (1) maintain the ISC database and the quality of data submitted by members, (2) maintain the proper function of ISC website, and (3) coordinate internal data sharing and develop protocols for answering external data requests, the STATWG is responsible for overseeing these functions in cooperation with WG chairs and members, providing a link to the ISC Plenary, and recommending appropriate actions when needed. Based on discussion at the July 6 and 7th meeting, the STATWG developed a work plan with 9 items as reported in section 6.1 of ISC/21/ANNEX/14. The STATWG recommended the following workplan for 2021-22 to the ISC21 Plenary:

- 1. The DA will continue to distribute the ISC data inventory for Category I, II, and III to ISC Data Correspondents for review by September 30, 2021. The DA will then distribute the ISC data inventory to Chairs of the species WG by October 15, and publish on the ISC website by October 31, 2021.
- 2. The DA will continue to archive stock assessment files from all 2020-2021 ISC assessments, which are required to be submitted by Chairs of species WG by November 1, 2021.
- 3. After the Data Correspondents have reviewed and updated their metadata prior to the ISC21 Plenary, this metadata will be published on the ISC researcher's website by August 31, 2021. For 2021-2022, the DA will continue to distribute the WG member's new metadata by March 30, 2022. The Data Correspondents will review and update their new metadata by July 1, 2022 prior to the ISC22 Plenary, and this new metadata will be published on the ISC researcher's website by August 31, 2022.
- 4. The DA will revise and update the User's Guide for Online Data Submission with the rules for using the data share space on the ISC collaborative research project database and research website. This revised information will be distributed to the Data Correspondents and WG Chairs by December 31, 2021. The DA will conduct training as necessary.
- 5. The DA and the Chair of the STATWG will annually review the responsibilities, duties and deliverables of the DA to ensure that they are accurate and practical, and revise them as necessary.
- 6. The DA and Chair of the STATWG will develop error-checking protocols to be used to post-data submission by Data Correspondents to confirm the quality of the data in the

- database. This protocol will be reviewed by the STATWG at ISC22.
- 7. The STATWG will pursue harmonizing the ISC data submission formats with those used by the WCPFC and the IATTC.
- 8. The STATWG Steering Group will hold an intersessional meeting or conference call/webinar January 2022 to conduct work to complete this work plan.
- 9. The STATWG Chair, Vice-Chair and other interested parties will continue to develop a NDA for data sharing requests. This NDA will incorporate comments from ISC21 and will be reviewed at the next STATWG meeting. A standard operating protocol will be developed to handle data sharing requests, which will include ISC point of contact information.

### **Discussion**

The Plenary thanked Jon Brodziak for his service as interim Chair of the STATWG, Sung-Il Lee for serving as Vice Chair, and Felipe Carvalho for assuming the role of Chair for the current term.

An interest in harmonizing the data submission formats with those used by WCPFC and IATTC was noted. The Plenary requested the STATWG report back at ISC22 on the use of Category II and III data, including the nature of data requests and usage by both ISC working groups and external parties. In the coming year, the STATWG Chair will formally assess data use.

With reference to the NDA for sharing stock assessment data files (discussed further under agenda item 6.2), currently in development, the Plenary confirmed that in the interim WG chairs who field requests for stock assessment data will consult with the ISC Chair on such decisions.

The Plenary endorsed the STATWG's proposed workplan and the data revision to SMA catches provided by Japan.

### 4.2 Total catch tables

K. Nishikawa, the Database Administrator, presented the annual catch tables for ISC Member countries for 2019-2020. The catch tables were prepared for the following ISC species of interest: albacore, Pacific Bluefin tuna, swordfish, striped marlin, blue marlin, blue shark, and shortfin mako shark. The catch tables were generated from the ISC database, and are based on Category I data (retained catch and released catch, when available) submitted by Data Correspondents for the major fisheries in the North Pacific Ocean of the member countries. Graphs of the historical catch by country were also presented for each species. Statistics for mean, minimum and maximum catch were also presented for each species for the latest five years. The complete catch tables are included in the ISC Plenary Report in Section 9 and serve as the official ISC catch tables.

### 5 REVIEW OF MEETING SCHEDULE

### 5.1 Time and Place of ISC22

The U.S.A. offered to host ISC22, 12-18 July 2022, as an in-person meeting in Kona, Hawaii. Associated WG meetings would be held beginning 8 July. The U.S.A. is exploring the possibility of accommodating a hybrid meeting format (where some Members could join remotely) to address any continuing travel restrictions on Members.

### 5.2 Time and Place of Working Group Intersessional Meetings

A draft schedule of proposed intersessional meetings was reviewed and amended. Proposed ISC WG and RFMO meetings are shown in the table below. Although some WG meetings are proposed to be in person, they may be switched to an online format due to continuing travel restrictions related to the COVID-19 pandemic. WG Chairs were asked to confirm with the ISC Chair the dates for their proposed meetings as soon as possible so the information can be posted on the ISC website.

### **6 ADMINISTRATIVE MATTERS**

### **6.1 ISC Stock Assessment Review Proposal**

The U.S.A. presented information on their proposal for advancing additional peer reviews of ISC stock assessments.

In the 2013 review of ISC's function, additional independent reviews of stock assessments were recommended. In 2018 the review of ISC's assessment review process provided recommendations for an additional review process. The purpose of this would be to increase transparency and improve the science. It was noted that the USA supports rigorous peer reviews and values external perspectives to improve science. ISC stock assessments are conducted by groups of highly trained, quantitative scientists. An additional level of independent review would serve to validate methods and approaches the Working Groups have taken, and occasionally identify additional issues of importance.

At ISC19, the Plenary agreed that alternative ways to integrate peer reviews into the stock assessment process and that associated costs should be identified. Following that meeting, the USA worked with the ALBWG Chair and Vice-Chair and the ISC Chair to develop a terms of reference for the review of the ALB assessment prior to ISC20, but the challenges of timing and structuring the review quickly became apparent and a review could not be organized prior to ISC20, given the timing of the albacore assessment.

The U.S.A. proposal identified those challenges, and the pros/cons of two approaches that were considered in the process. It was noted that the current review of ISC assessments is similar to the review processes used by other organizations who assess HMS stocks. Two scenarios presented for review, which have different purposes and differing timing. Scenario 1 was to conduct an additional review after an assessment is complete and prior to Plenary and would provide information on the quality of the assessment before it is considered by management. Scenario 2 is to conduct an additional review after an assessment is complete and following ISC Plenary and would provide information on how to improve the assessment in the future.

Not all assessments would be reviewed. It was noted that ISC could selectively choose which assessments to have reviewed based on a variety of factors, including time lapses since the last review, potential for science to result in new or significant management changes, economic impact, controversy, potential for precedent, and new or innovative research.

The U.S. concluded the presentation by posing several questions to Plenary: Do the 'pros' of an additional review process outweigh the 'cons'? If yes, which scenario would ISC members prefer?

### **Discussion**

The ISC Chair noted that the two scenarios described in the U.S. proposal have different objectives. Scenario 1 is intended to certify a stock assessment as the best available scientific information before consideration for management while Scenario 2 would identify improvements in the methodology that could be incorporated into a future stock assessment.

The Plenary discussed the two approaches but did not reach clear consensus on a preferred process, although the balance of the discussion favored the second scenario where peer review would occur after the Plenary meeting.

The Plenary clarified that the process for selecting a review panel would entail voting on candidates within the slates put forward by each Member funding a panel member rather than across all candidates. This approach is more feasible given the barriers to Member governments funding non-resident personnel.

The Plenary agreed that Members should continue to review the U.S. proposal and consider how to integrate stock assessment peer reviews into the ISC process. Members may further discuss a potential process administratively by email intersessionally. Over the next year the ISC Chair, in consultation with the U.S.A., will further develop the details of the Scenario 2 process, given stronger support for that approach in discussion. The Plenary will resume the discussion at ISC22 with the aim of agreeing on a preferred process.

### **6.2** Data Sharing Agreement

It was noted that the Plenary discussed this topic at ISC20 without reaching a resolution. A full draft of an NDA and related description of the process for determining access to stock assessment data was not available for review at ISC21 so a Plenary decision was deferred to ISC22. The Chair encouraged members to further consider the issue intersessionally so that substantial progress can be made at ISC22.

The STATWG Chair will investigate procedures used in other RFMOs along with further developing a draft NDA and report back at ISC22.

It was noted that an NDA is usually only required for access to confidential data. The presence of confidential data in stock assessment data files should be confirmed as part of further development of the NDA.

It was also noted that the ISC Operations Manual does not specify a process for sharing confidential stock assessment data and files. The ISC Chair indicated that he would be reviewing the Operations Manual and would bring forward a proposed process at ISC22.

### 6.3 Working Group Election results

The Plenary reviewed the current WG chair and Vice Chair terms as shown below. It was noted that Sarah Hawkshaw was elected Chair of the ALBWG and Felipe Carvalho was elected STATWG Chair. Mikihiko Kai was elected to a second term as SHARKWG Chair and Michael Kinney to a second term as Vice Chair.

**ISC21 FINAL** 

		First Election		Second Election	Second
Title	Name	Date	First Term	Date	Term
ISC Chair	John Holmes	Jul-17	2017-2020	Jul-20	2020-2023
ISC Vice Chair	Shui-Kai Chang	Jul-17	2017-2020	Jul-20	2020-2023
ALBWG Chair	Sarah Hawkshaw	May-21	2021-2024		
ALBWG Vice-Chair	Steve Teo	Jul-17	2017-2020	Apr-20	2020-2023
BILLWG Chair	Hirotaka Ijima	Jul-19	2019-2022		
BILLWG Vice-Chair	Yi-Jay Chang	Jul-19	2019-2022		
PBFWG Chair	Shuya Nakatsuka	Mar-19	2019-2022		
PBFWG Vice-Chair	SK Chang	Nov-19	2020-2023		
SHARKWG Chair	Mikihiko Kai	Apr-18	2018-2021	Jul-20	2021-2024
SHARKWG Vice-Chair	Michael Kinney	Apr-18	2018-2021	Jul-20	2021-2024
STATWG Chair	Felipe Carvalho	Jun-21	2021-2024		
STATWG Vice-Chair	Sung Il Lee	Jul-20	2020-2023		

# **6.4 ISC Organizational Chart**

The Plenary reviewed the organizational chart shown below and updated personnel as needed.

### ISC Organizational Chart (July 2021)

### Working Group Key:

1 Canada 2 China 3 Chinese-Taipei 4 Korea 5 Japan 6 Mexico 7 USA 8 PICES 9 SPC 10 IATTC 11 FAO 12 WCPFC VC Vice Chair DM Database Manager

This is not a comprehensive list but the main points of contact.

### 6.5 Other Matters

The ISC Chair thanked the WG Chairs and Vice-Chairs for their leadership and diligent work in advancing the goals of the ISC since ISC20. The quality of the work and science information and advice forwarded to the IATTC and WCPFC-NC by the ISC remains high. It is clear that the WGs have adapted to new methods of working virtually since none have requested sessions in advance of ISC22.

The ISC Chair also noted that he will be focusing on initiatives to move the ISC forward as an organization in 2021-22, including a review of the ISC Operations Manual to improve transparency and accountability, further development of the non-disclosure agreement for confidential stock assessment data and files, and developing more detailed proposals for the external review of ISC stock assessments. All of these proposals will be brought to ISC22 where they will be the subject of vigorous debate.

### 7 ADOPTION OF REPORT

The Report of the Meeting was adopted.

### 8 CLOSE OF MEETING

The meeting was closed at 8:30 PM PDT 19 July 2021.

### 9 CATCH TABLES

Table 5. North Pacific albacore (*Thunnus alalunga*) catches (in metric tons) by ISC member fisheries, 1952-2018. "0"; Fishing effort was reported but no catch: "+" - Below 499kg catch; "-" - Unreported catch or catch information not available. \* - Data from the most recent years are provisional.

Table 7. Annual catch of swordfish (*Xiphias gladius*) in metric tons for fisheries monitored by ISC member countries for assessments of North Pacific Ocean stocks, 1951-2018. "0"; Fishing effort was reported but no catch. "0" - Fishing effort was reported but no catch; "+" - Below 499kg catch; "-" - Unreported catch or catch information not available. \* - Data from the most recent years are provisional.

Table 9. Retained catches (metric tons, whole weight) by ISC Member countries of blue marlin (*Makaira nigricans*) by fishery in the North Pacific Ocean, north of the equator 1953-2020. "0" - Fishing effort was reported but no catch; "+" - Below 499kg catch; "-" - Unreported catch or catch information not available. \* - Data from the most recent years are provisional.

Table 10. Retained catches (metric tons, whole weight) by ISC Member countries of blue sharks (*Prionace glauca*) by fishery in the North Pacific Ocean, north of the equator, 1985-2020. "0" - Fishing effort was reported but no catch; "+" - Below 499kg catch; "-" - Unreported catch or catch information not available. \* - Data from the most recent years are provisional.
